Meetings to be held in the Nurses' Home of the Burbank Hospital, Fridays, at 4:30 p.m.

George P. Keaveny, M.D., *Chairman*
62 Fox Street, Fitchburg

The following questions will be discussed in the course on dermatitis and eczema:

1. Is there such a thing as eczema?
2. Is allergy fact or fiction?
3. Are skin tests of value in dermatology?
4. Are fungus infections (athlete's foot) as prevalent as we are led to believe?
5. With the diagnosis made, what should be the treatment of common cutaneous eruptions?

FACULTY FOR THE EXTENSION COURSES

Dermatology. Chairman: Dr. John G. Downing; instructors: Drs. John Adams, Jr., Leonard E. Anderson, Bernard Appel, J. Harper Blaisdell, G. Marshall Crawford, Francis P. McCarthy, Mildred L. Ryan, Jacob H. Swartz and Maurice M. Tolman.

Ear, Nose and Throat. Chairman: Dr. LeRoy A. Schall; instructors: Drs. Charles T. Porter, Lyman G. Richards and John R. Richardson.

Gonorrhea. Chairman: Dr. Oscar F. Cox; instructors: Drs. Weston T. Buddington, Sylvester B. Kelley and P. N. Papas.

Medicine. Chairmen: Drs. Chester S. Keefer and Robert T. Monroe; instructors: Drs. Fuller Albright, Clifford L. Derick, E. Stanley Emery, Eugene C. Eppinger, Marshall N. Fulton, G. Philip Grabfield, Franz Ingelfinger, Charles A. Janeway, Harold J. Jeghers, William T. Salter, Charles L. Short and Maurice B. Strauss.

Obstetrics. Chairmen: Drs. Meinolf V. Kappius and Roy J. Heffernan; instructors: Drs. Christopher J. Duncan, M. Fletcher Eades, A. Gordon Gauld, Thomas R. Goethals, James C. Janney, Foster S. Kellogg, Joseph W. O'Connor, Louis E. Phaneuf, John Rock, Judson A. Smith and Raymond S. Titus.

Pediatrics. Chairmen: Drs. Warren R. Sisson and James M. Baty. Instructors: Drs. Elmer W. Barron, John A. V. Davies, Louis K. Diamond, R. Cannon Eley, Joseph Garland, Harold L. Higgins, Lewis W. Hill, Edwin H. Place and Clement A. Smith.

Surgery. Chairmen: Drs. Howard M. Clute and Leland S. McKittrick; instructors: Drs. Hollis L. Albright, Arthur W. Allen, Franklin G. Balch, Jr., Marshall K. Bartlett, William E. Browne, Richard B. Cattell, Edward A. Edwards, Henry H. Faxon, Jacob Fine, E. Parker Hayden, Thomas H. Lanman, Robert R. Linton, Charles C. Lund, Champ Lyons, Henry C. Marble, Stanley J. G. Nowak, E. Everett O'Neil, Neil W. Swinton and Irving J. Walker.

Syphilis. Chairman: Dr. Francis M. Thurmon; instructors: Drs. William P. Boardman, Rudolph Jacoby and C. Guy Lane.

TEACHING CLINICS IN GONORRHEA AND SYPHILIS

The Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health and the

United States Public Health Service is again sponsoring teaching clinics in gonorrhea and syphilis. Registration in these teaching clinics is free; all expense of teaching is met by the sponsoring organizations. Clinic schedules are listed below; any legally registered physician in the Commonwealth may attend for one or more days.

Gonorrhea Clinics at the Boston Dispensary. These are open daily from 9:30 to 11:30 a.m., and on Monday, Wednesday and Friday evenings from 6:00 to 8:00. Dr. Oscar F. Cox is in charge. Write or telephone for additional information: Gonorrhea Clinic, Boston Dispensary, Boston.

Syphilis Clinics at the Massachusetts General Hospital. These are held in the Out-Patient Department, South Medical Service, on Tuesdays and Wednesdays from 10:00 a.m. to 12:00 noon. Dr. G. Marshall Crawford is in charge. Write or telephone for additional information: South Medical Service, Massachusetts General Hospital, Boston.

DEATHS

SUTHERLAND—JOHN P. SUTHERLAND, M.D., of Boston, died February 21. He was in his eighty-eighth year.

Born in Charlestown, he attended Boston schools and received his degree from Boston University School of Medicine in 1879. Following his graduation he started a practice in Concord and remained there for about two years before joining the faculty of Boston University School of Medicine, where he served as registrar before being appointed dean in 1900. He had also served as professor of medicine at his alma mater.

Dr. Sutherland was a member of the Massachusetts Medical Society and the American Medical Association. He had served as president of the Boston Homeopathic Society; a few years later he was elected president of the state organization and in 1904 was president of the American Institute of Homeopathy. After gaining international recognition in this field, he was chosen president of the International Council of Homeopathy. For fourteen years he was editor of the *New England Medical Gazette* and, at the time of his death, was on the editorial board of the *Journal*, having served for twenty years. He had served on the staff of the Homeopathic Hospital for nearly forty years, later becoming a trustee. He was also a member of the consulting boards of the Westboro State Hospital and the Worcester Homeopathic Hospital.

His widow survives him.

WARREN—FRANKLIN L. WARREN, M.D., of Bridgewater, died February 11. He was in his seventieth year.

Born in Shirley, he attended Lawrence Academy and Massachusetts State College, and received his degree from the University of Pennsylvania School of Medicine in 1899. Following his graduation he studied at the University of Edinburgh, Scotland.

Dr. Warren was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, a brother and a sister survive him.

MISCELLANY

ANNUAL MORTALITY SUMMARY FOR 1940

Deaths in eighty-eight major cities during 1940 were 1.6 per cent over the 1939 figures, according to preliminary reports recently made public by Director William L.

Austin, Bureau of the Census, Department of Commerce. The number of infant deaths increased 21 per cent, compared with 1939, but the infant death rate decreased slightly.

Deaths in the eighty-eight cities totaled 436,252, compared with 429,419 reported for 1939. The weekly death totals for the first two weeks in January, 1940, were dis-

TOTAL DEATHS BY WEEKS IN 88 MAJOR CITIES

tinctly lower than the averages for the preceding three years. During the second week in June, the last week in July and the first week in August, however, they showed a significant increase over the averages for the preceding three years. This increased mortality record in July and August was closely related to the heat wave that covered a large part of the country.

The 26,261 infant deaths reported for 1940 represent an increase of 537, or 2.1 per cent, over the 25,724 reported for 1939. On the basis of estimated number of births there were, in 1940, 39 infant deaths for each 1000 births. Although this figure is provisional, it indicates a slight decrease in infant mortality when compared with the provisional rate of 41 for 1939.

In the comparison of infant rates for different cities, certain considerations must not be overlooked. The effect of differences in sex, age and racial composition of different cities must be evaluated before valid comparisons can be made.

LOAN COLLECTIONS FOR TALKS BEFORE LAYMEN

The Bureau of Health Education of the American Medical Association offers to local physicians the loan of prepared material for speakers addressing lay audiences. Even though a physician may be an able speaker, he frequently hesitates to accept invitations to speak before lay audiences because time is required to prepare material in suitable language.

It is here that the clipping-collection loan service is of value. These collections consist of material that has appeared in *Hygeia*. They are patterned after the American Medical Association's Package Library. The advantage of this material is that it is written in nontechnical language that the layman can understand. Thus, the physician is saved the effort of translating technical material into language easily understood by nonmedical groups.

Collections on eighty-two topics are available accompanying most collections is a speaker's outline. This outline is not intended as a fixed pattern that the speaker must follow but is merely offered as one way in which the material may be presented. As the physician reads the clippings he may make his own notes on the outline

and use only that portion of the material appropriate to his community.

The collections may be borrowed for a ten-day period, and the only charge to the physician is the return postage for the bound material. Collections should be ordered at least two weeks in advance, and first, second and third choices should be indicated, since the collections are not always available.

The demand for this material has grown tremendously in the last several years. Several state medical societies, as well as a few county medical societies, have found it to their advantage to develop speakers bureau library services of their own. In spite of the great demand for this material and the amount of publicity it has received, there are still a number of physicians who are ignorant of its existence. The practicing physician is not always a polished platform orator and welcomes aid of this type.

The following loan collections are available:

Anesthesia	330 I
Anemia	92 I

Chicago, Illinois.

REPORT OF MEETING

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on December 3, 1940, with Dr. Aaron Thurman presiding. The speaker of the evening was Dr. Abraham Levinson, of the Northwestern University Medical School, Chicago. His

subject was 'Acute Infections of the Central Nervous System'

Dr Levinson enumerated the common causes of neurologic findings in children as follows: the onset of acute infectious diseases, meningitis, encephalitis and poliomyelitis; brain abscess, tumor, trauma, tetany, uremia and lead encephalopathy, tetanus and rabies, epilepsy, and poisonings. He gave several reasons for the difficulties encountered in the differential diagnosis of neurologic conditions in infants and children. The classic signs of meningitis may or may not be present in meningitides of the newborn and infants. Often the only manifestations are fever, bulging fontanelles and a cephalic cry. Nuclear icterus and cerebral hemorrhage are hard to differentiate from meningitis of the newborn. Lead encephalopathy should be considered in differential diagnosis. Another difficulty is the presence of unilateral symptoms in meningitis. These are due either to localized meningitis or to the presence of encephalitis in cases of meningitis. He mentioned tuberculous meningitis as a classic example of meningoencephalitis.

Dr Levinson then discussed diagnostic methods. Lumbar puncture, which formerly was employed almost invariably and too often, is now done too infrequently.

Careful study of the pellicle in the cerebrospinal fluid was urged, and the search for desquamated hexagonal cells, so-called 'Levinson cells,' was suggested. The glucose content of cerebrospinal fluid is diminished in bacterial meningitis, but is usually normal in the virus infections, such as mumps, and in syphilitic meningitis. The chlorides, although usually diminished in meningitis, he considered unimportant as a differential criterion. The Levinson test with sulfosalicylic acid and bichloride of mercury is useful in the diagnosis of tuberculous meningitis, but is not infallible. Cisternal fluid varies from lumbar fluid in cellular and sugar content, and should not be used for diagnosis.

The treatment of meningitis was then considered. Various forms and combinations of treatment have been advocated, and Dr Levinson reviewed his particular regimen. Initially, the patient is given sulfapyridine because it is beneficial in all types of meningitis. If there is no improvement in twenty-four to thirty-six hours, intravenous serum or antitoxin is administered in meningococcal meningitis. In general, combination therapy is employed, with the emphasis on chemotherapy. Sulfanilamide is used for the streptococcal form and sulfapyridine for the pneumococcal, with rabbit serum in the latter if the drug fails. Influenzal meningitis is treated with sulfapyridine. Fothergill's serum with complement has given promising results. The staphylococcal form has been attacked with sulfathiazole, sulfapyridine and serum, all in large doses. The dosage of sulfonamide preparations employed has been 4 gr per pound of body weight in the first twenty-four hours, half this amount being given immediately. The blood and cerebrospinal fluid drug levels are checked. Treatment is not stopped until the disease is well arrested, unless the toxic symptoms, such as anemia and hematuria, are marked. Tuberculous meningitis has recently been treated with calcium and vitamin D, the results have been questionable.

In mumps meningitis the symptoms are usually not marked, recovery is the rule, the cerebrospinal fluid sugar is normal and parotitis may not be present. Acute lymphocytic meningitis may at first simulate the tuberculous form, even so far as abdominal pain is concerned. It occurs mainly in the summer, and recovery is invariably complete and rapid.

Hemorrhagic encephalitis may run a rapidly fatal course. The cerebrospinal fluid is usually clear, the sugar

normal, and the globulin negative. In acute anterior poliomyelitis, the cerebrospinal fluid changes vary in the different stages of the disease. In the early systemic stage the fluid is usually normal. In the paralytic stage, there is usually an increase of amount, pressure, protein and cells. The early paralytic stage reveals essentially the same findings as the paralytic stage, but later the fluid returns to normal.

The speaker discussed tetanus, stressing the absence of fever unless there is secondary infection. For immediate prophylaxis he suggested the use of at least 3000 units of antitoxin for active immunization, two injections of toxoid. Therapeutically, he advised 40,000 to 60,000 units of antitoxin intravenously or intramuscularly or by both channels. Only one massive dose should be given. Since antitoxin merely prevents further involvement, sedation and constant nursing are especially important to counteract the symptoms. The use of Averin by rectum in doses of 25 to 80 mg per kilogram of body weight was suggested.

In regard to the drug treatment of convulsions, Dr Levinson reviewed the many available sedatives. He stated that chloroform is the best method of relief, and next to that some of the barbiturates intravenously. Magnesium sulfate was advised only in hypertensive encephalopathy. Hypertonic glucose has many drawbacks. Morphine is contraindicated because it increases intracranial pressure and thus masks the signs and symptoms.

The discussion was opened by Dr Edwin H. Place, of the Boston City Hospital, who observed that the spinal fluid changes of preparalytic poliomyelitis may simulate those of lymphocytic meningitis, but that this is of little significance if paralysis does not develop. Acute poliomyelitis affecting the proximal muscles of the four extremities may have the same type of fluid with greatly elevated protein. On the basis of the improvement shown in the treatment of meningococcal meningitis since the advent of chemotherapy, the mortality between the ages of five and forty-five years should be less than 10 per cent if early sulfanilamide therapy is carried out.

Dr Maxwell Finland, of the Boston City Hospital, discussed pneumococcal meningitis. He stated that although sulfapyridine is at present the most important single therapeutic agent, antiserum plays a large role in many cases that would not otherwise recover. Despite the fact that there is a real question whether any form of drug introduced intrathecally acts as more than an irritant, the almost miraculous recoveries with intrathecal serum in addition to complement, after all other forms of therapy have failed, still keep the question open. Sulfathiazole penetrates slowly, especially into the cerebrospinal fluid, whereas sulfanilamide is better in this regard. In general, one is apt to encounter toxic symptoms in attempting to attain high enough levels in the spinal fluid.

Dr Wilfred Bloomberg, of the Boston City Hospital, reiterated the importance of not introducing irritating substances promiscuously into the spinal canal. He stated that chloride of very low values may be found in tuberculous, even in the absence of many cells, whereas the lowest values have been observed in cases of meningismus with elevated pressure and no increase in cells. A low sugar content in some verified cases of virus meningitis has been demonstrated in contrast to the usual findings. Dr Bloomberg suggested therapeutic lumbar punctures for the lowering of pressure rather than the intravenous injection of hypertonic solutions.

The discussion was closed by Dr Levinson, who stated

that the foci of infection should be removed in all infections of the central nervous system. He agreed that intrathecal chemicals are irritating and result in a sterile meningitis. Sterilization of the blood stream should be the aim of therapy. High levels of drugs are not always necessary to effect a cure, since the permeability of the meninges is increased in meningitis. In answer to Dr. Bloomberg, it was stated that changes of chloride merely mirror some physiologic changes in the blood. And since there are so many cases with low chloride values, they cannot be considered diagnostic of tuberculous meningitis. Finally Dr. Levinson remarked that caffeine is beneficial in lowering intracranial pressure and may be used to advantage after such procedures as encephalography.

NOTICES

MEDICAL AND SURGICAL SUPPLY COMMITTEE

It will help England greatly in the care of victims of bombing raids and help England prepare for the coming invasion, if physicians in this country will give discarded or superfluous surgical instruments or surgical dressings.

Any such material should be sent to the Medical and Surgical Supply Committee, 420 Lexington Avenue, New York City.

PETER BENT BRIGHAM HOSPITAL

Dr. I. S. Ravdin, Harrison Professor of Surgery at the University of Pennsylvania School of Medicine, will serve as surgeon-in-chief *pro tempore* at the Peter Bent Brigham Hospital from March 10 to 15.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM, MARCH

- Tuesday, March 4—Optimistic Outlook in the Treatment of Leukemias. Dr. W. P. Murphy.
Wednesday, March 5—Hospital case presentation. Dr. S. J. Thannhauser.
Thursday, March 6—X-ray Studies of Less Common Gastrointestinal Lesions. Dr. R. Schatzki.
Friday, March 7—Allergy: A problem in immunology. Asthma: A problem in physiology. Dr. F. M. Rackemann.
Saturday, March 8—Hospital case presentation. Dr. S. J. Thannhauser.
Tuesday, March 11—Psychiatric Examination of Recruits. Dr. A. W. Stearns.
Wednesday, March 12—Hospital case presentation. Dr. S. J. Thannhauser.
Thursday, March 13—The Enzymatic Breakdown of Carbohydrates. Dr. G. Schmidt.
Friday, March 14—The Neurologic Complications of Some of the Common Contagious Diseases. Dr. R. C. Eley.
Saturday, March 15—Hospital case presentation. Dr. S. J. Thannhauser.
Tuesday, March 18—Syphilis and the Spinal Fluid. Dr. W. A. Hinton.
Wednesday, March 19—Hospital case presentation. Dr. S. J. Thannhauser.

- Thursday, March 20—Tobacco and Peripheral Vascular Disease. Dr. J. S. Sprague.
Friday, March 21—Arthritis clinic. Dr. W. Bauer.
Saturday, March 22—Hospital case presentation. Dr. S. J. Thannhauser.
Tuesday, March 25—Handwriting in Neurology: Psychiatry. Dr. J. C. G. Loring.
Wednesday, March 26—Hospital case presentation. Dr. S. J. Thannhauser.
Thursday, March 27—Syringomyelia. Dr. H. H. Merritt.
Friday, March 28—Some of the Medical Aspects of Care of Patients with Rheumatic Fever and Rheumatic Heart Disease. Dr. T. D. Jones.
Saturday, March 29—Hospital case presentation. Dr. S. J. Thannhauser.

HARVARD MEDICAL SOCIETY

There will be a meeting of the Harvard Medical Society on Tuesday, March 11, in the amphitheater of the Peter Bent Brigham Hospital at 8:15 p.m. Dr. Ellis C. Cutler will preside.

PROGRAM

Presentation of cases.

Some Aspects of the Physiology of the Liver and Biliary Passages. Dr. I. S. Ravdin, Harrison Professor of Surgery, University of Pennsylvania School of Medicine.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and staff meeting of the New England Hospital for Women and Children will be held on Thursday, March 6, at 7:15 p.m. in the classroom of the nurses' residence. Dr. Grace E. Rochford will preside.

PROGRAM

Three case reports of diverticulitis. Dr. Grace E. Rochford. Discussion by Drs. Katherine S. Andrews and Ann P. Manton.

NEW ENGLAND SOCIETY OF ANESTHESIOLOGY

The March meeting of the New England Society of Anesthesiology will be held in the White Auditorium, Massachusetts General Hospital, on Tuesday, March 11, at 8 p.m.

PROGRAM

Ten Years' Experience with Avertin. Drs. G. A. Leonard and R. F. Sheldon.

NEW ENGLAND HEALTH INSTITUTE

The New England Health Institute, in collaboration with the health departments of the New England states, the United States Public Health Service, the United States Department of Labor Children's Bureau, the New England Tuberculosis Association, the Massachusetts Public Health Association and the Massachusetts Central Health Council, will hold its eleventh session at the Hotel Statler, Boston, on April 2-4. Those desiring detailed information should apply to the Massachusetts Department of Public Health, State House, Boston.

BOOK REVIEWS

Diagnosis and Treatment of Head Injuries By Sidney W. Gross, M.D., and William Ehrlich, M.D. Introduction by Percival Bailey, M.D., Ph.D. 8", cloth, 275 pp., with 94 illustrations. New York: Paul B. Hoeber, Incorporated, 1940 \$5.00

The average physician is called on more and more to treat craniocerebral injuries, for which he has had no special training. This book aims to serve as a readily available consultant to those who see the occasional head injury. The perplexing problem in such cases is the great clinical similarity in the early stages of severe and mild injuries when considered from the pathological standpoint. Hence, one wishes that the authors might have spent more space discussing the diagnostic problems that arise in the fresh case, omitting some of the more detailed discussion of operative cases, which are seldom treated by the men for whom the book was supposedly written.

The authors' attitude on lumbar puncture is halfway between those who say "never" and those who say "always." Sometime these two opposing schools should come to a sound physiologic compromise. The present treatise evades the issue and does not give the complete answer.

This book will be particularly useful in the library of the small hospital, since it is a handy reference for the physician who is required to treat an occasional case of head injury.

Psychological Studies in Dementia Praecox By Isabella Kendig, Ph.D., and Winifred V. Richmond, Ph.D. 4", paper, 211 pp., with 25 graphs and 8 tables. Ann Arbor, Michigan: Edward Brothers, 1940 50 cents (distribution costs).

The title might more precisely read "Psychometric Studies," since the work deals fully and competently with the reaction of schizophrenic patients to the 1916 Stanford-Binet scale. To follow most of the work it is necessary to have considerable knowledge of this procedure, as well as acquaintance with the general principles of intelligence testing. Some 500 patients with schizophrenic reactions are specially studied, with control material from other pathologic groups as well as from comparable normal persons. Much attention is paid to the patterns of responses, the study of which demands more than ordinary effort, since the Binet scales are only partly suited thereto.

The principal conclusion is to minimize in these conditions the role of intellectual deterioration in the sense of an irreversible process. Not only are reversals to be observed, but with a little ingenuity much intellectual functioning can be elicited that is inaccessible to the conventional examining technic. Shock therapy arrived a little late for a considerable part of the work, but its confirming implications are recognized. Relevant literature is well cited; there should have been an index.

Aux confins de la dyspepsie. By Maurice Loeper. 8°, paper, 308 pp., with 33 illustrations. Paris, Masson et Cie, 1940. \$1.85.

In his introduction the author offers the thesis that only rarely is dyspepsia—or what we usually refer to as indigestion—a symptom of intrinsic gastric disease. The entire volume is an attempt to describe the large variety of clinical conditions, other than those concerning the stomach directly, in which indigestion may play some part. Practically all systems are covered with lengthy clinical discussions and with some attempt to explain why the symptom originates. Little new material is offered, either in the way of facts or of original observations. The author has succeeded in conveying the impression that indigestion is a practically constant concomitant of almost every disease, regardless of whether the intestinal, genitourinary, cardiorespiratory, endocrine or central nervous system is primarily involved. The theme running through the entire volume is that the patient with indigestion should be thoroughly investigated for the underlying cause of his illness and not considered merely from the point of view of that symptom; furthermore, the therapy should be directed mainly at the underlying cause.

An Atlas of the Commoner Skin Diseases. Second edition. By Henry C. G. Semon, D.M. (Oxon.), F.R.C.P. (London). 4°, cloth, 273 pp., with 120 colored plates. Color photography under the direction of Arnold Moritz, M.B., B.C. (Cantab.). Baltimore: Williams and Wilkins Company, 1940. \$12.00.

The first impression that one receives on thumbing over the pages of this atlas is that it is alive. It is a welcome escape from the museum-type of colored atlases of photographs of the moulages of the past. To study the natural-colored photographs of these lesions is the next best thing to attending the clinic itself. This is by far the best collection of colored plates of common dermatoses that the reviewer has seen. The selection of the dermatoses that are illustrated is excellent, and the descriptions quite succinct.

One can, however, find some controversial elements in numerous minor details, particularly in the discussion of therapy. Although the photographic technic on the whole is excellent, the quality of the illustrations is variable. This is perhaps reasonable, but the plates that can be criticized are those in which the depth of the field is too short—a flaw that could have been remedied by using a smaller stop with more illumination. Because the photography was under the direction, not of the medical author, but of an expert, it is reasonable to expect technical results higher than the average. The reviewer cannot resist the temptation to state that there is probably a greater degree of technical ability in color-plate reproduction in the American press, particularly in the field of magazine illustration, than that shown by these illustrations. For those who require a relatively accurate representation of the common dermatoses, this volume can be highly recommended.

The Public Health Nurse and Her Patient. By Ruth Gilbert. 8°, cloth, 396 pp. New York: The Commonwealth Fund, 1940. \$2.25.

This thoughtfully written book commands the attention of the physician as well as that of the public-health nurse for whom it was written. Begun as a sort of handbook of the principles and the application of mental hygiene in nursing practice, it developed into a general discussion of the whole subject of the human relation between the nurse and her patient. The author, who is supervisor of social work in an organization devoted to community psychiatric service, writes of mental hygiene in public health nursing, of caring for the sick patient, of teaching health, of the nurse and the maternity patient, of the child and his family, and of the nurse's relation to her co-workers. The field is very broad.

The result is a kind of dignified and specialized "How to Win Friends and Influence People." Such advice is not only hard to give; it is even more difficult to follow. Nurses, as well as physicians, who are outstandingly successful in their human associations, are born, not made. Even though such a book as this cannot be expected to make good public-health nurses of poor ones, its effect will be excellent if it serves merely to attract to the field those who are qualified by temperament to serve in it.

The New International Clinics: Original contributions, clinics and evaluated reviews of current advances in the medical arts. Edited by George Morris Piersol, M.D. Vol. III, New Series Three. 8°, cloth, 358 pp., with 87 figures, 17 tables, and 14 charts. Philadelphia: J. B. Lippincott Company, 1940. \$3.00.

This book contains a variety of original contributions and clinics that maintain the high standard to which we have become accustomed.

Among the original contributions are the following: "Emotional Factors in Coronary Disease and Angina Pectoris," "The Pathology of Urogenital Tuberculosis," "Present Concepts of Erythrocyte Sedimentation Rate," "The Significance of Rectal Pain," "Congenital and Acquired Sex Changes" and "Mikulicz' Disease."

The clinic presentations include Heuer's paper on the treatment of gallstone disease, emphasizing the advantages of early diagnosis and treatment. Papers concerning the electrocardiographic changes in pulmonary infarction, the treatment of bleeding peptic ulcer, the use of sulfanilamide in obstetrics, the treatment of cryptorchidism and numerous brief articles on other timely subjects are also to be found in this volume.

An excellent review of ten years' progress in obstetric analgesia from the Department of Obstetrics of Johns Hopkins University makes this an altogether worthwhile addition to the previous editions.

The Practice of Medicine. By Jonathan Campbell Meakins, M.D., LL.D. Third edition. 4°, cloth, 1430 pp., with 562 illustrations, including 48 in color. St. Louis: C. V. Mosby Company, 1940. \$10.00.

This work has now become an established medical text and is widely recognized as one of the leading books in its field. The author has made a few changes in the third edition, but the book is essentially the same as it was when first published in 1936. The outstanding feature of numerous illustrations, as compared with the amount of text, has been maintained. Unfortunately, the publisher has also retained the green-tinted paper of poor quality. The book, however, is still to be highly recommended.

THE MANAGEMENT OF THE COMPLICATIONS OF PEPTIC ULCER*

T. GRIER MILLER, M.D.†

PHILADELPHIA

THE important complications of peptic ulcer are perforation, hemorrhage, cicatricial stenosis and, in gastric ulcer, malignant degeneration. Their management, in a broad sense, involves not only procedures designed to restore their victims to good health but also measures to prevent their development. This necessitates, in the first place, a brief consideration of the treatment of simple uncomplicated peptic ulcer.

Although perforation or hemorrhage occasionally represents the first manifestation of peptic ulcer, it is exceedingly uncommon for either of them to develop in a person on an adequate ulcer program; this is not necessarily true for obstruction or malignant degeneration, but at least good ulcer therapy constitutes the only available means of avoiding any of the complications.

What, then, is a proper peptic-ulcer regimen? To be rational it must be based on an appreciation of the fundamental etiology of ulcer. That, unfortunately, is not known, though little by little physicians have acquired knowledge of some of the predisposing or associated factors, which, however, are difficult to evaluate.

Thus it has been known for a long time that an acid gastric secretion is essential to ulcer formation; that ulcers, at least superficial ones of the stomach, often develop in the presence of severe debilitating disease, such as an acute general infection; and that gastritis and local vascular lesions are frequently associated. At the same time it is appreciated that an acid gastric secretion is normal and that the degree of acidity may be as high in a normal person as in one with an ulcer; that the gastric ulcers of debilitating diseases are usually recent and superficial, by no means similar to the chronic ulcers commonly seen in practice; and that gastritis and local vascular lesions may be secondary as well as primary developments.

Today, attention is focused more largely on the person who has the ulcer than on his stomach or duodenum: on his heredity, his physical, mental and emotional make-up, the nature of his endocrine and autonomic nervous system equipment, his social status and his personal habits of life. The thin, lantern-jawed, hungry-looking person with a nervous, introspective and sensitive temperament is the one likeliest to develop peptic ulcer. Draper, Dunn and Seegal¹ say that such a person has little endurance, but is quickly rehabilitated by food, short periods of rest and sleep. Sometimes he shows imbalance of the sympathetic and parasympathetic nervous systems or some endocrine disturbance. These patients, it is found, frequently develop ulcer when subjected to unusual emotional strain, to continued worry and anxiety, to fatigue, to loss of sleep, to improper food or to the excessive use of tobacco or alcohol.

On such a theory as to etiology, the therapy of simple peptic ulcer is largely based today. One still attempts to keep the gastric acidity under control, but not necessarily neutralized. This is accomplished by frequent feedings rather than by alkalis. Nothing can be done about hereditary or constitutional factors, but much emphasis is placed on keeping the patient at ease, avoiding physical and nervous strains, rearranging the social environment, and providing for good nutrition, the careful mastication of food and the avoidance of foods and drinks that are mechanically or chemically irritating. The situation is much the same as in active pulmonary tuberculosis. The patient has a chronic disease, and he must reorganize his whole life for the future, even for the periods when he has no active lesion, since recurrences and complications are common. Local measures are often of great importance in both diseases, but it is equally important for the ulcer patient as well as the tuberculous patient to develop a philosophical attitude, to conquer his natural tendency to fret and worry and to avoid excessive responsibilities

*Presented at the meeting of the New England Postgraduate Assembly, Cambridge, Massachusetts, November 14, 1940.

†Professor of clinical medicine, University of Pennsylvania School of Medicine.

and undue nervous and physical strain. He must at the same time appreciate the necessity of a change in his habits of eating, give up alcohol and tobacco, if addicted, and acquire a fixed and leisurely routine of life.

Such a program is not easy. It is far more difficult than merely securing a few weeks' rest in bed, giving a series of hypodermic injections, extracting teeth, removing tonsils or administering alkalis along with milk and cream.

These things apply primarily to the management of simple ulcer cases and constitute the essentials for the prevention of the complications of peptic ulcer. They apply equally to the treatment of the complications, but are overshadowed by the indications for more radical therapy.

Of the complications, perforation is the most dramatic, and its therapy is entirely surgical. The internist's sole duties in a case of acute perforation are promptly to make the diagnosis and to secure a competent surgeon. In the subacute case the diagnosis may be difficult and may require much time and study, but the therapeutic indications are surgical and need not receive further consideration here.

Pyloric obstruction, on the other hand, is not always an indication for surgery. It may be due to spasm, an acute inflammatory swelling about the ulcer, edema incident to a low blood-plasma protein or to cicatricial contraction. Only when the lesion is proved to be permanent is surgery indicated. Before that decision is made the patient deserves a period of bed rest for the first few days, with constant suction on the stomach contents to keep the organ empty, and fluids, including, if necessary, whole blood or blood plasma, by vein. Such intravenous injections are especially indicated if the plasma protein of the blood is low. Liquid and soft foods, including some protein, should be given by mouth as soon as possible. In some cases it may be possible to intubate the small bowel and feed into the duodenum or jejunum. Hot applications, preferably moist, are often helpful in relaxing spasm, and sometimes belladonna is effective. Only when, after such a period, the obstruction persists, as shown by continued symptoms or roentgenologic study, should surgery be employed. In such cases of persistent organic obstruction of the pylorus, surgery is clearly indicated, and a gastroenterostomy is usually sufficient to bring about permanent relief.

Hemorrhage is the third and commonest complication of peptic ulcer. Its incidence is not known. In the literature one finds statements to indicate that it occurs in 20 to 40 per cent of cases, but these are based largely on hospitalized cases, which

include only the severest and most of those with extensive hemorrhage. On the other hand, many ambulatory patients have small hemorrhages that give rise to no symptoms, so that their feces are rarely examined.

Severe hemorrhage, in any event, does not often develop in the patient who is on a proper ulcer regimen. I do not believe that I have observed a hemorrhage of significant severity in a case under adequate treatment, except when the patient has been subjected to some unusual emotional strain or after some other digression from his routine of management. Prevention, therefore, is largely a matter of keeping the patient on his ulcer program.

When marked hemorrhage does occur, one should first of all decide whether it is primarily a medical or a surgical problem. That will depend more largely on one's training and experience than on any available data from the literature on the subject. Some surgeons believe that all such cases should be operated on within twenty-four to forty-eight hours; Finsterer² reported a mortality of only 5.9 per cent in a series of cases so handled. Other surgeons, notably Dr. Arthur W. Allen, of Boston, prefer to wait until the hemorrhage has ceased, but under certain conditions,—elderly patients who continue to bleed for two days,—Dr. Allen³ operates in the midst of the hemorrhage; his mortality is 14 per cent. In spite of early operation, some surgeons have had a high mortality, even 60 per cent (Ross⁴). Dr. Allen has had a mortality of 33 per cent in his patients past fifty years of age. We have delayed operation until it was obvious that, except by means of a radical procedure, the patient would die; we have had only 5 such cases, and the patients all died following operation. For 383 operated cases collected from the literature Elsom and I⁵ found a mortality of 28 per cent.

On the other hand, for 5843 patients treated medically, we found the mortality to be only 8.7 per cent, ranging for the different authors from 0 to 25 per cent. In most cases the medical treatment has consisted of bed rest, starvation and morphine for the period of active bleeding, followed by the Andresen or the Sippy regimen. On this program, in our series of 49 cases, there was a mortality of 6.1 per cent. If we add to these our patients operated on after the cessation of hemorrhage, there were 63 cases, with a mortality of 6.3 per cent.

Five series of cases, totaling 116, are reported in which no deaths occurred⁶⁻¹⁰; all of these were treated by prompt feeding. Meulengracht's¹¹ total series of 491 cases, all treated by prompt and

fairly adequate feeding, had a mortality of only 2 per cent, and if to this are added other cases treated by his technic (a total of over 861 cases), the mortality is only 2.3 per cent. It seems, therefore, that his procedure deserves special consideration.

Meulengracht feeds his patients from the time of their hospitalization, even while still bleeding, and gives them six feedings a day of a generous diet, including ground meats, vegetable purées, bread and butter, tea and cereals. His program is based on the observations that exhausted underfed patients often die of hemorrhage and that patients often stop bleeding in spite of feedings, and on the opinion that an empty stomach with free acid is not conducive to the healing of an ulcer.

I was not greatly impressed by Meulengracht's regimen at first, and suspected that he had included all cases with bleeding, but when I learned that a third of his cases had a hemoglobin reading of less than 50 per cent and that other clinicians using his feeding regimen were getting similar results, we cautiously began to feed our patients, even in the midst of hemorrhage. I confess that we have usually started with a somewhat simpler dietary but have rapidly included all the articles he advised. We have now had 28 cases with but 1 death—a 4 per cent mortality; the average hemoglobin reading was 41 per cent. In one case the bleeding kept up for a week, and several transfusions were necessary to maintain a safe blood level. We finally operated because of the continued bloody stools, but at operation no blood was found in the stomach or duodenum and the resected ulcer showed fresh healing. Our series is small and with a larger one we may have less favorable results, but at least I am convinced that the feeding program is as safe as starvation, and certainly the patients, instead of being in an exhausted state and poor operative risks, are cheerful, contented and in good condition for any subsequently required operative procedure.

Undoubtedly some patients will not survive any conservative program, and perhaps some of them could be saved by prompt operation, but it is impossible to pick out such cases in advance; if all are operated on, the mortality, even in Finsterer's hands, is far greater than the medical mortality on the newer program.

Let me make one other point in reference to the therapy of hemorrhage. It has been the custom to give morphine freely to the acutely bleeding cases. Morphine, however, secondarily relaxes the duodenum, which is unfavorable to the cessation of hemorrhage. Some such drug may be necessary to quiet the fears of certain patients, but I have usu-

ally found the barbiturates, orally administered, equally effective and devoid of at least a theoretical objection. This point deserves further observation.

Furthermore, I doubt the necessity of alkaline medication in bleeding ulcers and suspect that often it is a factor in the disturbed chemical condition of the patient. Our patients have seemed to do equally well without any such medication.

Finally we come to the question of malignant degeneration in gastric ulcer. Palmer¹² believes that such a change never occurs, but that ulceration develops in primarily malignant lesions and that the malignant ulcer was always malignant. Other gastroenterologists and pathologists, however, believe that a benign gastric ulcer may undergo secondary malignant change, and they therefore consider the malignant lesion a complication. The answer is uncertain, but at least some ulcers of the stomach are malignant, perhaps 5 to 10 per cent or more.

Such a lesion, whether a peptic-ulcer complication or not, is always to be managed surgically, unless, of course, it is obviously inoperable. The internist's primary duty consists in making the diagnosis, and that is far from easy. The gastroscope has been a great help, but even that procedure is by no means infallible. Roentgen study often can establish the diagnosis, but not always in the early case, and it is only in the early case that one has a chance of curing the patient. Dr. Sara Jordan,¹³ of Boston, has emphasized the significance of repeated roentgenologic studies, but even when the ulcer niche decreases with time one cannot be sure that the diminution has not resulted from filling of the crater with cancer tissue. The size of the lesion has been regarded as significant, all those larger than a fifty-cent piece being considered malignant, but everyone with experience has known far larger lesions to heal rapidly and permanently on a simple medical regimen. Dr. George W. Holmes,¹⁴ of Boston, has rendered a great service by emphasizing the importance of the location of the lesion, those about the pylorus and along the greater curvature usually being malignant and those of the mid-lesser curvature benign.

The final decision of when to operate is difficult, and one must take into consideration all the factors mentioned: size, location, roentgenologic and gastroscopic observations, response to therapy and the general state of the patient. I do not know the answer and have made mistakes both ways. One should tend always to err, if one must, on the side of safety for the patient.

Finally, among the complications, though it is

not strictly speaking a complication, is the refractory ulcer case—the type that, for some reason, does not respond to the usual sort of ulcer therapy. Such cases deserve, first of all, complete bed rest for a period of weeks, antispasmodics, sedatives, a strict dietary program and perhaps alkalies. In these alone I have found it helpful to introduce a tube into the stomach from time to time to determine definitely whether the gastric acidity is completely controlled. In such a way, some patients can be relieved of symptoms, but even they usually have a recurrence under the slightest provocation, and in most cases finally come to operation. In these a gastroenterostomy is usually of no permanent help; only a properly performed gastric resection gives a satisfactory result.

PELVIC DELIVERY UNDER LOCAL INFILTRATION ANESTHESIA*

CHARLES P. SHELDON, M.D.†

BOSTON

IN 1913, Gellhorn¹ advocated the use of local and spinal anesthesia in gynecology and obstetrics. In 1916 King² described a technic of perineal anesthesia in labor. Although Gellhorn,³ Rose,⁴ Torland,⁵ Greenhill,⁶ O'Connor,⁷ Walker,⁸ and Urnes and Timmerman⁹ advocate local anesthesia for pelvic delivery, the method has never become popular in this country. In 1938 Bushnell¹⁰ sent questionnaires to ninety-six outstanding obstetricians scattered throughout the United States. An analysis of seventy-three completed questionnaires revealed that local anesthesia was used in only seven institutions.

Greenhill¹¹ and Adam¹² describe the many advantages of local anesthesia. When properly used the method has been proved to be efficacious.^{4, 8, 9} Because of the simplicity and obvious safety of local-infiltration anesthesia in obstetrics, it is hard to understand why the technic has not been more generally adopted. By and large, doctors are reluctant to use local anesthesia for pelvic delivery for the following reasons: the value of complete amnesia during labor is overemphasized; lack of understanding in the preparation of novocain (procaine hydrochloride) solutions is a common deterrent; local anesthesia requires more constant surveillance of the patient in labor than is necessary for some of the methods of analgesia and anes-

thesia now in vogue; it cannot be successful unless the operator is familiar with the anatomy of the female perineum and external genitalia.

ANATOMY

The nerve distribution in the female perineum and external genitalia is shown in Figure 1. The pudic nerve leaves the pelvis through the great sacrosclatic foramen, passes along the outer aspect of the spine of the ischium, accompanies the pudic vessels upward and forward along the outer wall of the ischio-rectal fossa in a sheath of the obturator fascia called Alcock's canal, and divides into the perineal nerve and the dorsal nerve of the clitoris. The inferior hemorrhoidal nerve branches off the pudic trunk before its terminal division. These nerves pass through the ischio-rectal fossa and supply the skin of the perineum, the labia minora, the greater part of the vagina, a part of the labia majora and parts of the anus.

The small sciatic nerve also emerges from the pelvis through the great sacrosclatic foramen and supplies the skin of the perineum and of the back part of the thigh and leg. It gives off the inferior pudendal nerve, which curves forward below the tuberosity of the ischium, pierces the fascia lata, and proceeds forward beneath the superficial perineal fascia to supply the skin of the labia, communicating with the superficial perineal and inferior hemorrhoidal branches of the pudic nerve.

The ilioinguinal nerve issues from the external

*From the Department of Obstetrics, Harvard Medical School, and the Boston Lying-in Hospital.

†Assistant in obstetrics, Harvard Medical School; assistant obstetrician to outpatients, Boston Lying-in Hospital.

abdominal ring and supplies the skin of the upper and inner part of the thigh and the skin of the labia.

The pelvic branches of the second, third and fourth sacral trunks run forward on either side of the rectum, unite with the sympathetic ganglion that lies between the rectum and the cervix, and supply the bladder, the uterus, the upper part of the rectum and the lower part of the pelvic peritoneum.

The technic of infiltration anesthesia outlined in this paper blocks the branches of the pudic nerve,

ing for three to five minutes or by autoclaving for five minutes at five pounds' pressure. Whenever possible the solution should be made with sterile physiologic saline solution. Uniformly good results are obtained with a 1 per cent solution.

For home delivery, the solution may be prepared in the following manner: A 250 cc. Pyrex Erlenmeyer flask is immersed in boiling water for ten minutes. To the sterile flask is added about 100 cc of sterile normal saline solution or ordinary boiled tap water and ten novocain "A" tablets (Winthrop). The mouth of the flask is covered

the inferior hemorrhoidal nerve, the perineal branches of the small sciatic nerve and the labial branch of the ilioinguinal nerve

EQUIPMENT

Novocain

A considerable part of the success of this method depends on the proper preparation of the novocain solution. Most hospitals subject novocain solutions to the sterilizing technic that is used for dry goods and other equipment. This often results in a partial decomposition of the product so that it is inferior from the anesthetic stand point and may also contain elements that have a mildly toxic effect on the tissues.¹⁴ Ideally, novocain solutions should be prepared the day they are used and should be sterilized either by boil-

ing with a sterile gauze square, held in place by a rubber band. The solution is then brought to a boil. When cool, it is ready for use.

Novocain "A" tablets contain suprarenin, which gives the solution a hemostatic effect and also prolongs its anesthetic action. If pure novocain is used, 10 minims of a 1:1000 solution of adrenalin should be added to each 100 cc of solution. Solutions containing epinephrine should not be subjected to prolonged boiling or autoclaving, because epinephrine is not heat stable. Novocain-suprarenin solutions in ampules are convenient for delivery in the home.

Syringes and Needles

Any 10-cc glass syringe will suffice for the injection of the novocain solution, but a needle-

locking syringe, such as the Luer-Lok type, is advantageous.

There should be three sizes of needles. A 1¼-inch, 24-gauge Yale hypodermic needle, is used for intracutaneous and subcutaneous injections (Fig. 1). Three-inch, 20-gauge and 5-inch, 20-gauge Luer-Lok needles are desirable for infiltration of the deeper tissues. An ordinary hypodermic needle, a Wassermann needle and a spinal-puncture needle can be used perfectly well if the needles recommended are not available. The needles should have a short bevel, so that there will be less likelihood of puncturing blood vessels.

CONDUCT OF LABOR

No standard procedure is utilized for the selection and dosage of analgesic agents used during labor. Roughly, however, the first stage of labor is divided into three phases.

Phase 1. As soon as it is established that the patient is in true labor and that the contractions are causing distress to the patient, a sedative is administered. If it seems likely, from an evaluation of the type of contractions and of the dilatation of the cervix, that labor will continue for more than four hours, ⅛ gr. morphine sulfate and 1/200 gr. scopolamine hydrobromide are given subcutaneously.

Phase 2. In the middle of labor, as the action of the morphine and scopolamine wears off and more medication is needed, Seconal or pentobarbital sodium in doses of 3 to 4½ gr. will give the necessary relief. The former acts quickly and has a shorter action and is thus quite satisfactory for the conduct of these cases.

In some patients, this and the first phase merge into one another, and the labor appears to be one that will progress rapidly. In these cases the morphine, and often the scopolamine, are omitted.

Phase 3. The latter part of the first stage of labor can be made quite bearable for the patient by administering a few breaths of nitrous oxide with each pain. The face mask is removed after the contraction passes. Gas analgesia is continued until the baby's head strikes the pelvic floor. Ether, with each contraction, is satisfactory for the conduct of home delivery. In 1916 Hoag¹⁵ proposed the combined use of scopolamine, nitrous oxide and oxygen, and local infiltration for pelvic delivery. His perineal infiltration was, however, inadequately performed.

Local anesthesia cannot be properly utilized if the patient receives analgesic and amnesic drugs during labor in amounts that produce irrationality, restlessness and inability to co-operate. Inhalation analgesia is ideal because of its transitory effect,

thereby making it possible for the patient to receive relief from pain and still retain the ability to co-operate when expulsive efforts are needed in the second stage. Inhalation analgesia is omitted when patients are comfortable without it or if the patient suffers from lung disease, such as acute upper respiratory infection, pneumonia or pulmonary tuberculosis.

It may not be feasible to produce analgesia during labor in the home. Local anesthesia is particularly desirable in these cases because it renders the actual delivery process essentially painless and affords the patient much relief that otherwise would not be available.

TECHNIC OF PERINEAL INFILTRATION

Since parasacral conduction anesthesia and pudic block¹⁶ are technically too difficult for the average doctor engaged in obstetric practice, an attempt has been made to develop a technic of local infiltration that can be simply done and will nevertheless be effective from the patient's standpoint. It is not greatly different from the method originally described by King² and later used by Torland,⁵ Walker⁸ and Urnes and Timmerman.⁹

A multiparous patient should be infiltrated as soon as the cervix is fully dilated, unless there is good reason to believe that the second stage of labor will be prolonged because of mild disproportion, unrotated posterior position or the like. A primiparous patient is infiltrated when the baby's head strikes the perineum and begins to distend the vulval tissues.

Preparation of the Patient for Delivery

The patient receives nitrous oxide and oxygen while the perineum is being prepared. This prevents the pain associated with the contact of chemical solutions with the vulvovaginal tissues. This discomfort lasts only two or three minutes, and the inhalation is therefore carried out only for a comparable length of time. Inhalation analgesia is omitted during preparation of the patient for delivery if nonirritating solutions—soap and water and 1 per cent Lysol or 1:5000 mercury bichloride—are used, which is usually the case in deliveries in the home.

Area of Infiltration

Five wheals are made at points demonstrated in Figure 1. The nerves are then blocked according to the following technic.

The labial branches of the ilioinguinal nerves are anesthetized by injecting 5 cc. of novocain solution downward toward the external abdominal ring from Wheal I and fanned out in an area above and lateral to the clitoris.

Through guidance of a finger of the gloved hand in the vagina, the pudic, inferior hemorrhoidal and inferior pudental nerves are anesthetized by inserting the 3-inch needle at Wheal II and injecting 10 cc. of novocain solution into an area medial and posterior to the ischial tuberosity. The plunger of the syringe is drawn back to determine whether the needle is in a blood vessel, because intravenous injections may cause undesirable reactions.

Infiltration of the ischiorectal fossa is best done with the five-inch needle. The area of infiltration should be fan shaped and should extend from the pubic ramus above to a line connecting the anus with the ischial tuberosity below. Infiltration medial to the descending ramus of the pubic bone blocks those branches that escape the deep injection at Wheal II. Approximately 10 cc. of solution is needed for infiltration of the ischiorectal fossa. This infiltration is always carried out with the needle in motion to avoid intravenous injections.

Through Wheal III a crescent-shaped area of infiltration of the perineum is made above and lateral to the anus. The rectovaginal septum is then infiltrated upward and laterally for a distance of 5 or 7 cm. under guidance of a finger in the vagina. Infiltration of the perineum and rectovaginal septum requires another 10 cc. of solution.

The amount of solution injected at various points is only roughly approximate, and the total varies between 50 and 70 cc.

CONDUCT OF THE DELIVERY

The five original skin wheals are satisfactorily placed for the application of towel clips to hold the sterile drapes in position during delivery.

If nurses or other attendants support the patient's legs, this will contribute to her comfort and facilitate delivery. A small pillow in the lumbar region helps to prevent backache.

Following the above infiltration, the patient is allowed to bear down with the contractions for fifteen or twenty minutes before anything active is done about delivery. At this time, if delivery is not progressing rapidly, an episiotomy is performed, sterile green soap solution is instilled in the vagina, and the forceps are gently applied to the baby's head. With succeeding contractions, gentle traction is exerted on the forceps at the time the patient bears down. Traction is discontinued as the contraction passes. Unless there is cephalopelvic disproportion or malrotation of the head, the delivery is promptly carried out. One or two minims of posterior-pituitary extract will often obviate forceps delivery.

It is almost never necessary to give inhalation analgesia at the time of contractions after the infiltration has had time to take effect. On the other hand, a few breaths of nitrous oxide and oxygen or ether with each pain will suffice to control patients with nervous dispositions.

One-sixth grain of morphine sulfate is given subcutaneously as soon as the baby is born.

After delivery the perineum is expeditiously sutured. If the perineal laceration extends beyond the level of the original infiltration, a slight amount of solution injected at the upper angle will promptly produce anesthesia of the rectovaginal tissues so that the laceration can be repaired without discomfort to the patient.

Expulsion of the placenta completes the delivery.

PRACTICAL CONSIDERATIONS

Period of anesthesia. Anesthesia is usually adequate for one and a half to two hours from the time of infiltration.

Local tissue relaxation. The local infiltration of tissues with novocain produces muscular relaxation. This facilitates delivery and helps to prevent extensive episiotomies or perineal lacerations.

Blood loss. Since the patient is not under general anesthesia, local tone of the uterine muscle remains normal, with the result that bleeding is the same as in delivery without anesthesia. The suprarenin in the novocain solution prevents, through its action on the blood vessels, excessive bleeding from the perineal tissues.

General condition of the mother. The removal of pain stimuli with local anesthesia and the performance of episiotomy and low-forceps delivery avoid maternal exhaustion associated with a prolonged second stage of labor and the dangers that inevitably accompany inhalation anesthesia. The pulse rate and blood pressure are almost invariably comparable before and after delivery.

Very often, even with no inhalation analgesia at the time of the contractions, the mother has no sensation whatever of the birth of the baby, yet she is aware that she plays a part in the birth process because she pushes the baby out of the birth canal, either with or without assistance from the attending physician. She can see her baby as soon as it is born, and this often makes a profound and desirable impression on her psyche.

Condition of the baby. The baby responds to the birth process under local anesthesia just as if the delivery were conducted without anesthesia. In some respects it is probably in better condition, because the second stage of labor is shortened, thereby avoiding undue molding of the head and diminishing the dangers of cerebral anoxia. The

baby breathes and cries spontaneously and promptly in 95 per cent of the cases, often crying before the entire body is delivered. That atelectasis may occur from depression of respiration from anoxemia due to causes other than analgesia and anesthesia is indubitable, but atelectasis should be exceedingly rare when babies are delivered under local anesthesia. Furthermore, the gentleness that is possible in performing forceps delivery with infiltration anesthesia diminishes to a minimum the dangers of cerebral damage.

CONCLUSIONS

Assuming that local perineal anesthesia has not been used extensively in obstetrics because of a lack of appreciation of the ease with which deliveries may be conducted with this method, an attempt has been made to outline in some detail the exact technic of delivery under local anesthesia that, in the author's hands, has been eminently satisfactory in 64 cases. If the details of the conduct of labor and delivery outlined above are as scrupulously observed as the details recommended by surgeons in performing thyroidectomy under local anesthesia, the method is almost always successful. The preparation of the novocain solution, the conduct of the labor and the execution of the delivery are as important as the method of perineal infiltration. The procedure is, however, technically within the scope of any physician qualified to undertake obstetrics.

It is believed that small doses of sedatives during labor, in addition to local anesthesia for delivery, give the most satisfactory results in normal and low-forceps deliveries. Furthermore, spontaneous breech deliveries,⁹ manual rotation of the head, Scanzoni's operation,⁸ the delivery of face and brow presentations after flexion, and even mid-forceps deliveries can often be conducted under local infiltration anesthesia.

CARCINOMA OF THE ESOPHAGUS DEVELOPING IN BENIGN STRICTURE*

EDWARD B. BENEDICT, M.D.†

BOSTON

ALTHOUGH the etiology of carcinoma of the esophagus is unknown, the fact that trauma and chronic irritation may play a part in its development, as elsewhere in the body, is evidenced by the occasional development of carcinoma in a benign stricture. In the literature 31 cases of carcinoma developing in benign lesions are reported. To these I add 2 cases of my own, from a total of 40 cases of carcinoma. A complete tabulation is given in Table 1.

Certain comments on the table mentioned above are indicated. Statistically the figures are not of great value, since they are incomplete, not only in the total number of cases of esophageal carcinoma,

but also in the etiology of the stricture. In 220 cases of carcinoma of the esophagus (Feilchenfeld,⁵ Redlich,⁷ Bejach,⁹ Benedict), benign stricture was considered a predisposing factor in 12, an incidence of 5.5 per cent. Actually the incidence is probably very much lower than this, for of course many physicians seeing carcinoma of the esophagus may never see a case arising in a benign lesion. Of 33 cases listed above, 16 are known to have occurred following lye burns. In many others, the etiology is not given. Röpcke's³ case, which followed trauma and scarring owing to a bone fragment, is most interesting and, apparently, very unusual. Vinson's¹⁶ cases associated with cardio-spasm and hysterical dysphagia are of interest but not altogether convincing. Indeed, in his recent

tion with other obstructive lesions"; and later, in discussing complications of hysterical dysphagia, he says, "Carcinoma has not occurred with sufficient frequency in patients with hysterical dysphagia to justify the assumption that the two conditions are related etiologically." He therefore seems to have modified his earlier opinion. Rake,¹⁹ on the other hand, reports having seen 3 cases of carcinoma of the esophagus that arose in association with achalasia of the cardia. He postulates the theory that achalasia, or failure of the cardia to relax, leads to stagnation, esophagitis, shallow ulcers, epithelial hyperplasia and benign papillomas that eventually become malignant. This theory applies equally well to the occurrence of carcinoma in any benign stenosis of the esophagus. In any event, a lye burn is the one outstanding type of benign esophageal lesion that seems to play a role in the later development of carcinoma.

My first case, however, concerns a patient whose carcinoma arose in an area of congenital stenosis.

CASE REPORTS

CASE 1. D. G. (P. H. No. 162587), a 58-year-old man, was admitted to the Phillips House on November 14, 1938,

complaining of inability to swallow food. The history dated back to infancy. He had always regurgitated, and at the age of 17 had been unable to tolerate solid food until bougies were passed. Since then there had always been more or less difficulty in swallowing, although the patient had been able to get along quite satisfactorily until 1 month before entry, when he began to have low substernal distress. For 4 days before entry, he had been

FIGURE 1. Case 1.

X-ray appearance of a carcinoma of esophagus developing in a congenital stricture.

unable to take adequate amounts of food and had regurgitated blood-streaked material, together with all food eaten.

Physical examination revealed no relevant findings.

X-ray examination of the esophagus (Fig. 1) was interpreted as follows:

There is an annular constriction of the esophagus, about 5 cm. long, just below the bifurcation of the trachea; the esophagus above it is considerably dilated, and there is visible peristalsis in it, and at times spasmotic contraction. The outline of the esophagus above the constriction is somewhat blurred, suggesting prominent mucosal folds. In the constricted area, the margins are distinctly ragged, and normal mucosa is not visible. Below the involved area, the esophagus appears normal. There is no evidence of an extrinsic mass. Films of the chest show no evidence of disease

in the lungs, pleura or mediastinum. The heart shadow is moderately enlarged. Conclusions: the examination shows moderate enlargement of the heart, stricture of the esophagus at the junction of the middle and lower thirds and dilatation of the esophagus above the stricture; it also shows changes in the mucosal pattern, which could be due to either an inflammatory process or a new growth.

Esophagoscopy under local anesthesia on November 16 was reported as follows:

The upper esophagus showed some thickening and reddening of the mucosa, indicative of chronic

FIGURE 2. Case 1.

Pathologic fracture of the scapula—metastatic from a carcinoma of the esophagus.

esophagitis. At a point 35 cm. from the upper incisors, there was marked narrowing of the lumen, with a red, slightly nodular and slightly ulcerating lesion that appeared to involve the right lateral wall, and part of the anterior and posterior walls. Several specimens of tissue were taken from this region. Esophageal bougies (No. 12 to No. 20) were passed through the stenotic area into the stomach; No. 20 was definitely tight. There was only a small amount of bleeding.

The biopsied specimens were reported as showing no evidence of cancer. The examination was therefore repeated on November 25, when more satisfactory specimens of tissue were obtained; these were reported as showing highly undifferentiated carcinoma (Grade IV). In spite of x-ray treatment, esophagoscopy and tube feeding through an inlying duodenal tube, passed at

the time of esophagoscopy, the patient failed very rapidly, and died on January 6, 1939.

An interesting complication in this patient was the development of a pathologic fracture through the neck of the scapula, sustained when he was being moved from his bed to a litter. X-ray examination of the scapula (Fig. 2) on November 28 was reported as follows:

The films show a fracture through the neck of the scapula; and near the lower border of the scapula, in the region of the fracture, there is a round, sharply defined area of diminished density, about 1 cm. in diameter, which has the general appearance of a metastatic nodule. The other bones visible on these films show no evidence of disease.

Autopsy. Post-mortem examination showed epidermoid carcinoma (Grade IV) of the esophagus, with metastases to the mediastinal, retroperitoneal and mesenteric lymph nodes, and to the liver, kidney, jejunum, pleura, vertebrae and scapula.

The highly undifferentiated epidermoid carcinoma apparently developed in this patient in the region of an old congenital stricture. There was no history of ingestion of lye, or of a foreign body, yet the difficulty in swallowing dated from infancy. The conclusion therefore seems justifiable that this carcinoma arose in an area of chronic irritation, produced by a congenital stricture. The diagnosis was positively established by esophagoscopy, and bouginage was carried out under direct vision through the esophagoscope.

CASE 2. H. W. (B. M. No. 226639), a 35-year-old man was admitted to the Baker Memorial Hospital on December 5, 1939, complaining of difficulty in swallowing of 34 years' duration. At the age of 15 months he swallowed lye and required a gastrostomy for feeding. Dilatations of the esophagus were performed, so that he was finally able to swallow solid food. However, about once a year food would stick in his throat and bouginage was necessary.

Physical examination was essentially negative.

X-ray study of the esophagus (Fig. 3) on December 8 was reported as follows:

The esophagus shows diffuse reduction in its size, as well as five constrictions about equally distributed from the upper orifice to the lower orifice. There is no peristaltic activity at any point in the esophagus. The upper end shows the most marked constriction. The mucosa of the segment of the esophagus, about 5 cm. in length, just opposite the episternal notch, appears grossly irregular, and at one point there is a definite ulcer, about 1.5 cm. in diameter. This ulceration apparently lies on the right posterior wall and is surrounded by an area of induration, about 3 cm. in length. There is no obvious soft-tissue mass, and the trachea is neither displaced nor deformed. The lower end of the esophagus is the next smallest point, but this does not produce obstruction. There is a diaphragmatic hernia. Conclusions: the picture is extremely complicated owing to the old diffuse fibrosis secondary to the ingestion of lye; I believe that the lesion in the upper end that appears ulcerated is due to carcinoma.

Esophagoscopy under local anesthesia was done on December 6. This was before the x-ray study. It was reported as follows:

The epiglottis was normal. The arytenoids and vocal cords were of normal size and motility. The lesion could not be demonstrated with the esophageal speculum. A 9-45 esophagoscope passed about 1 cm. beyond the cricopharyngeal muscle, where it met obstruction by a constricting lesion, apparently a benign stricture. Esophageal bougies (No. 10 and No. 12) passed through the stricture for a distance of about 15 cm., where they met some resistance; No. 12 was tight. No view could be obtained beyond the stricture of the area suspected of being cancerous. It

pathological report, however, esophagoscopy was repeated, December 12, and reported as follows:

The esophagoscope passed readily to a point about 2 cm. below the cricopharyngeal muscle, where it met complete obstruction. The small lumen previously established was readily visualized. Esophageal bougies (No. 8 to No. 22) passed without difficulty through the stricture; No. 24 seemed tight and could not be passed. After dilatation of the narrowing, it was impossible to see clearly any nodular lesion, but the ball forceps and cutting forceps were passed through the stricture; specimens were taken of the region beyond the stricture. At least five or six satisfactory specimens were obtained, and had the appearance of cancerous tissue.

The pathological report was slowly growing epidermoid carcinoma (Grade 1).

Following the second esophagoscopy, there was further improvement in swallowing, and the patient was able to take an adequate soft-solid diet. He gained so much in weight and strength that an attempt at esophagectomy was advised. A preliminary jejunostomy was performed January 6, 1940. On February 5, the esophagus was explored through a transverse neck incision and also through a thoracotomy incision. The upper edge of the tumor was felt at the thoracic inlet, but the esophagus could not be separated from the trachea, because of adhesions. The lung was also adherent and intimately fused to the mediastinum. The mediastinum over the esophagus and trachea was a firm mass of inflammatory tissue. The esophagus, therefore, could not be isolated either above or below the tumor, so that the attempt at esophagectomy was abandoned. Following operation, the temperature, pulse and respirations were elevated, with sepsis in the neck wound. From this point on he failed rapidly, and died February 22. Autopsy was not permitted.

In this patient there was a history of the ingestion of lye at the age of fifteen months, followed by multiple strictures of the esophagus, with development of epidermoid carcinoma (Grade 1) after a lapse of about thirty-four years. Biopsy through the esophagoscope was difficult in this patient owing to narrowing above the site of the neoplasm. After dilatation, however, a satisfactory biopsy was obtained. Esophagectomy was impossible owing to multiple adhesions, presumably largely the result of the lye injury.

CONCLUSIONS

Two cases of carcinoma of the esophagus developing in benign stricture are reported. One arose at the site of a congenital stricture, the other at the site of a lye burn.

The literature has been carefully reviewed, and the possible etiologic factors briefly discussed. Carcinoma developing in a benign stricture is rare. It has been more commonly reported following lye burn than in association with any other type of benign stricture.

The importance of esophagoscopy under local

FIGURE 3. Case 2.

Multiple lye strictures of the esophagus, with carcinomatous degeneration of the upper stricture.

was not thought wise to attempt the removal of tissue blindly through the stricture. Tissue from a slight roughening of the mucosa on the posterior wall proximal to the stricture was removed and sent in Bouin's solution to the laboratory. Conclusions: probably benign stricture of the upper esophagus due to lye; carcinoma not excluded.

The pathological report showed no evidence of carcinoma.

Following the dilatation, the patient's swallowing was very much improved. Because of the negative

anesthesia in the diagnosis and treatment of these cases is emphasized.

INTRAVENOUS DRIP ADMINISTRATION OF AUTONOMIC DRUGS*

ABRAHAM MYERSON, M.D.,† AND JULIUS LOMAN, M.D.‡

BOSTON

RECENTLY the introduction of drugs into the body by the method of intravenous drip has received great impetus by the work of Hirshfeld, Hyman and Wanger,¹ Hyman and Hirshfeld² and others.³⁻⁶ The advantages of the drip method are obvious. Not only may subtoxic amounts of drugs be infused at any desired rate, but a continuous action of a drug may be maintained for a long time. Furthermore, the undesirable reactions following massive administration of a drug may be prevented by slow intravenous infusion. For example, in the treatment of asthma, a single large dose of epinephrine may produce a severe reaction, whereas repeated doses of the drug may stop the asthmatic attack if it is severe or prolonged. Colmes⁷ has demonstrated that slow intravenous drip of adrenalin may overcome these disadvantages in the treatment of severe cases of asthma.

In the treatment of other conditions, the method of intravenous drip offers possible advantages. Thus it occurred to us that a group of autonomic drugs, the actions of which one of us⁸ has studied intensively, might have clinical usefulness when given by slow intravenous infusion. Accordingly we studied the effect by this method of certain drugs: adrenergic or sympathomimetic and cholinergic or parasympathomimetic.

The patients were passive cases of dementia praecox; their general physical condition was

good and their pharmacologic reactions were known to us from previous work in autonomic pharmacology.

The drugs were added to physiologic saline solution. The rate at which the solutions were given depended on the effects obtained; it was varied from patient to patient and was easily controlled by means of a Kelly drip tube interposed in the infusion system. The effect that served as a guide with the adrenergic drugs was a rise in blood pressure and its constant maintenance at the desired level, and with the parasympathomimetic drugs, either moderate sweating or a definite drop in blood pressure. In every case the time of the experiment lasted from one to two hours.

RESULTS

Adrenergic or Sympathomimetic Drugs

Amphetamine (Benzedrine) sulfate. Any desired level of blood pressure was maintained with solutions containing 50 mg. in 200 cc., depending on the rate of administration. As with the intravenous or intramuscular injection of amphetamine sulfate,⁹ the pulse rate showed no change, unless the blood pressure was raised to moderate or high levels. A typical experiment is as follows:

J. H. At 9:55 a.m. the blood pressure was 132/80, the pulse rate 72. Amphetamine sulfate was started at about 30 drops per minute. At the end of 7 minutes the blood pressure was 148/90, the pulse rate 68. In 15 minutes the blood pressure was 160/90, the pulse rate 68. One half hour after the experiment started, at 15 drops per minute the pulse rate was still 68, the blood pressure 164/90. In 1 hour the blood pressure had reached 176/100, the pulse rate was 68, and the rate of administration was reduced to 12 or 15 drops per minute. The

blood pressure then remained at the level of 176/100 until the end of the experiment, 2 hours after its inception.

Thus in this patient, as in the others in whom this drug was used, it was possible to maintain a uniform hypertension with from 15 to 30 drops a minute—a relatively small amount of liquid that could not in any way overburden the heart or circulation. In most patients, increased talkativeness occurred.

Beta-para-hydroxyphenylisopropylamine (Paredrine). Since Paredrine has a relatively more powerful effect on the blood pressure than amphetamine sulfate,¹⁰ weaker concentrations were used than with the latter drug. Thus 20 mg. of Paredrine in 200 cc. of physiologic saline, given at a rate ranging between 20 and 50 drops a minute, maintained the blood pressure at a high level for any desired period. As with amphetamine sulfate, slowing of the pulse depended on the height of the blood pressure.

Propadrine hydrochloride. Propadrine was given in stronger concentrations than the former two sympathomimetic drugs because of its relatively less powerful effect on the blood pressure. Thus 200 mg. in 200 cc. of physiologic saline at a rate varying between 30 and 60 drops a minute gave the desired increases in the blood pressure. The pulse rate diminished, depending on the degree of increase of blood pressure. The results obtained with Propadrine, as with Paredrine, differed from those with amphetamine sulfate in that psychologic effects were absent.

Adrenalin. One to 2 mg. of adrenalin in 200 cc. of physiologic saline solution, given at a rate between 20 and 30 drops a minute, caused an increase in the blood pressure. With the rise in blood pressure, however, the patient experienced discomfort, which was associated with pallor and weakness. Diminution of the rate of administration caused sudden falls in blood pressure and a disappearance of the undesired side effects. This drug, because of its rapidity of action, seemed more difficult to control than amphetamine sulfate, Paredrine or Propadrine.

Cholinergic or Parasympathomimetic Drugs

Acetyl-beta-methylcholine chloride (Mecholyl). From 10 to 20 mg. of Mecholyl in 200 cc. of physiologic saline was used. The mild effects of the drug,—that is, sweating, salivation, lacrimation, increased pulse rate and diminution of blood pressure,—could be obtained in any degree, depending on the rate of infusion; mild sweating and salivation could be obtained so that little, if any, effect on the vascular system resulted. When the drug was given at a greater speed, the latter changes

could also be obtained. These results corroborated previous experiments in which it was shown that an increased rather than a diminished pulse rate was the usual effect of small doses of Mecholyl.¹¹ One of the patients had urgency of urination during the administration of the drug. It is to be kept in mind that with the administration of Mecholyl by any method, atropine sulfate should be ready for intravenous administration to check ill effects, since some people are definitely oversusceptible to the drug.

Furfuryl trimethyl ammonium iodide (Furmethide). Furmethide was given in doses of 50 mg. in 100 cc. of physiologic saline. This drug, which we previously studied,¹² showed many of the parasympathomimetic effects that follow the administration of Mecholyl, that is, flushing, sweating and increased pulse rate. Unlike Mecholyl, however, it caused a slight increase in the blood pressure. The degree of effect of the drug could be readily maintained according to the speed of infusion.

SUMMARY

The sympathomimetic drugs, amphetamine (Benzedrine) sulfate beta-para-hydroxyphenylisopropylamine (Paredrine) and Propadrine hydrochloride may be given by the intravenous drip method for a prolonged period. A rise in blood pressure to a desired level can easily be obtained, and can be maintained indefinitely. The effect obtained with adrenalin is not so satisfactory as that with amphetamine sulfate, Paredrine or Propadrine, since it is difficult to maintain a continuous hypertension without undesirable side effects.

The parasympathomimetic drugs, acetyl-beta-methylcholine chloride (Mecholyl) and furfuryl trimethyl ammonium iodide (Furmethide), may likewise be administered by the intravenous drip method, producing constant physiologic effects over a prolonged period, the rate of the effect being proportionate to the rate of drip administration.

From the clinical point of view, the drip method of administering the sympathomimetic drugs may be useful. For example, amphetamine sulfate, Paredrine or Propadrine may be added to fluids given during the course of operations when it is desirable to increase or prevent a fall in blood pressure. For such purposes these drugs may be more useful than adrenalin in certain cases.

Amphetamine sulfate, as we have shown elsewhere,^{13, 14} has an opposing effect on the action of the barbiturates. We suggest, therefore, its utilization by the drip method in the treatment of barbiturate intoxication.

Since Mecholyl and other parasympathomimetic drugs are useful in the control of postoperative distention of the bladder and bowel, it is also suggested that the drip method may be efficacious in controlling these complications.

CARCINOMA OF THE CERVIX*

A Review of 200 Cases Treated with Radium

GEORGE C. WILKINS, M.D.†

MANCHESTER, NEW HAMPSHIRE

ALL the cases of carcinoma of the cervix reviewed in this paper were treated with radium only, and the therapy administered by the author or his associate, Dr. George F. Dwinell. With the exception of the few cases treated during the first two years, in which the dose was somewhat less than that subsequently adopted, the therapeutic dose given and the method of application have been practically uniform throughout. There have been minor technical modifications of the routine application methods, and there have been minor variations in the total irradiation dose, necessitated by individual requirements. All patients treated from 1920 to 1934 are included, and all were followed until five years had elapsed without known recurrence or until death ensued.

The total number of patients treated was 200. Of these, 185 had primary carcinoma of the cervix, and 15 had carcinoma of the cervical stump. The five-year survival in the patients with primary carcinoma of the cervix was 70 out of 185, or 37 per cent, whereas that of the patients with carcinoma of the cervical stump was 3 out of 15, or 20 per cent. Of the 73 patients living over five years, 30 have survived from ten to nineteen years after treatment.

The average age of the patients with primary cervical carcinoma was forty-nine years, the youngest being twenty-six and the oldest eighty-four.

The average age of patients with carcinoma of the stump was fifty-two years, the youngest being thirty-four and the oldest sixty.

In all cases the diagnoses were confirmed by slides from specimens taken before treatment was instituted. Grading was not adopted by the pathologist as a routine procedure until 1930, so that no grading tabulation can be included in this

TABLE 1. Classification of Cases According to Involvement.

	TOTAL CASES		CASES SURVIVING 5 YEARS	
	NO.	PER CENT	NO.	PER CENT
Stage I	38	20	24	63
Stage II	21	11	11	52
Stage III	98	53	35	35
Stage IV	28	15	0	
Totals	185		70	

review. Squamous-cell carcinoma was the histologic finding in every case of primary carcinoma of the cervix, whereas in the 15 cases of carcinoma of the stump, adenocarcinoma and an unidentified carcinoma were each found in 1, and squamous-cell carcinoma in 13.

Each primary carcinoma of the cervix was graded according to the amount of involvement of the cervix and adjacent tissues, using the League of Nations classification as a basis. The number of cases and the results of treatment in each stage are shown in Table 1. These figures are both interesting and informative, and correspond well with similar reports by other clinicians. They

*Read by title at the annual meeting of the New England Surgical Society, Poland Spring, Maine, September 27-28, 1940

†Surgeon, and director of cancer clinic, Elliot Hospital, Manchester

also confirm the oft-repeated statement that curability of cancer depends on early recognition and early treatment. The mortality rate increased proportionately with tissue involvement.

The table demonstrates the preponderance of Stage III (moderately advanced) cases. Greater curability in early carcinoma is proved by the fact that 63 per cent of the Stage I patients survived. Even this percentage is a little low, but is accounted for by 2 of the Stage I patients who were only twenty-six years old and did not survive. Only 1 patient under thirty years of age survived, and she is living without recurrence twelve years after treatment. As might be expected, there were no survivals among the Stage IV patients.

Although we have used x-ray therapy in addition to radium in the treatment of carcinoma of the cervix since 1934, the cases here reviewed and treated from 1920 to 1934 received only radium therapy. The basic principles of radium therapy, adopted early, have been continued without change.

Each patient was given $\frac{1}{2}$ gr. of Pantopon and $1\frac{1}{2}$ gr. of Nembutal one hour before the treatment, and no general anesthesia was used unless the patient was very unco-operative. The cervical canal was slowly and carefully dilated with Hanks dilators. Using 100 mg. of radium in two brass screens (2.0-mm. wall), 75 mg. was placed in the cervical canal and 25 mg. just above, for twenty hours. The second day following this, another treatment was given with the same amount of radium in a T tube, with 50 mg. in the canal and 50 in the crosspiece, the crosspiece being either anteroposterior or transverse, as indicated by the location of the lesion. This applicator remained for eighteen hours. With all treatments, the vagina was firmly packed with gauze and an inlying catheter placed in the bladder. Three weeks later, the third and last treatment was given, usually a repetition of the first, for eighteen or twenty hours. These three treatments totaled 5600 to 5800 milligram hours.

It is believed that the spacing of treatments is important. It was found that the first two treatments, given within forty-eight hours of each other, and totaling 3800 milligram hours, were about all a patient could have without producing too intense bladder or rectal irritation. It was found that in three weeks practically all radium reaction had subsided; this was considered the best time for a third treatment, one that would

deliver another blow to any cancer cells that had not received a lethal dose.

The importance of this timing, which was decided on empirically, was subsequently found to approximate closely the theory of Coutard regarding the periodicity of susceptibility of cancer cells to irradiation.

In 9 of the 15 cases with carcinoma of the cervical stump, the supravaginal hysterectomy had been performed from two to fourteen years previously, and these can be considered as primary carcinomas of the stump. The other 6 obviously had carcinoma when operated on, since they came for treatment from one to twelve months after operation. In only 2 cases was there a definite pathological history of carcinoma in the uterus at the time of operation. In the others various reasons for hysterectomy were given, such as inflammation, fibroid and flowing (4 cases). The average duration of symptoms in the stump cases before treatment was six and a half months, somewhat less than the average for the cases with primary carcinoma. This tendency to seek examination earlier is probably because any flowing or discharge after hysterectomy is more alarming to the patient than abnormal flowing with the uterus intact.

Since 1934, we have treated an increasing number of cervix cases with the same radium technic, but with the addition of preliminary deep x-ray therapy to the pelvis through five ports, 1800 r to each port; it is hoped that in a few years another comparable group may be presented to evaluate the final results with the addition of x-ray therapy to the same radium technic.

SUMMARY

An analysis of results of radium treatment in 200 consecutive patients with carcinoma of the cervix is presented. All patients were treated with practically the same technic and dosage, given by one or the other of two physicians.

Total five-year survivals in 185 patients with primary carcinoma of the cervix numbered 70, or 37 per cent. Total five-year survivals in 15 patients with carcinoma of the cervical stump numbered 3, or 20 per cent.

It is hoped that a further report may be presented later, in which these results will be compared with those in a series in which the same radium technic will be supplemented by preliminary deep x-ray therapy.

ENCEPHALOPATHY ASSOCIATED WITH SULFAMETHYLTHIAZOLE THERAPY*

EPHRAIM ROSEMAN, M.D.,† AND CHARLES D. ARING, M.D.‡

CINCINNATI

SO-CALLED "hemorrhagic encephalitis" is a frequently described pathologic picture, the cause of which has been attributed to many etiologic agents. The commonest causative factors are the heavy-metal compounds, such as the arsphenamines, and some of the alkaloids, especially those of the opiate group.¹ The morbid process resulting from intoxication by these chemicals is fairly uniform in each case. In the central nervous system, widespread damage of the smaller radicals of the vascular bed usually occurs. As a result, one finds extensive ring-shaped perivascular hemorrhages, confined for the most part to the white matter. Alpers,² Russell,³ Glaser, Imerman and Imerman,⁴ Alexander and Putnam⁵ and Roseman and Aring⁶ have pointed out the presence of focal perivascular areas of necrosis in addition to the perivascular hemorrhages in the encephalopathy produced by arsphenamine. This necrotic process may completely dominate the microscopic picture, so that the classic hemorrhagic phenomena, usually described on gross examination, may be entirely absent.

We are recording the clinicopathological findings in a case of hemorrhagic encephalopathy that occurred after the oral administration of sulfamethylthiazole. The report of such a complication has not been noted in the literature. The pathologic picture is unique in that the perivascular hemorrhages were confined rather rigidly to the gray matter of the cerebral hemispheres and to the gray structures of the brain stem. This localization is peculiar because the typical hemorrhagic encephalitis is confined chiefly to the white matter. The indications are that the precipitating factor of the sulfamethylthiazole encephalopathy may be a toxic reaction on the vascular bed of the central nervous system.

CASE REPORT

W.F., a 32-year-old Negro, was admitted to the Medical Service of the Cincinnati General Hospital on February 19, 1940, with a diagnosis of left-lower-lobe pneumonia. The patient had been enjoying fair health until

February 12, when he developed a mild upper respiratory infection. On February 16, while at work, he was seized with a severe pleuritic pain in the left chest, and he developed a cough. He felt quite ill and was sent to bed by his employer. On February 18 he had a severe, shaking chill followed by exacerbation of the chest pain and expectoration of blood-tinged sputum. At this time his wife noted that the patient appeared to be somewhat confused. A physician, summoned the following day, ordered the patient to the hospital.

The past history was of significance in that he had been employed as a shaker in a lead factory for 15 years, and hence had probably inhaled large quantities of lead dust. However, there was no history of colic, constipation, anemia or nerve palsies. The patient had enjoyed excellent health until 2 months prior to admission, at which time easy fatigability, weakness, a nonproductive cough and loss of weight were noted. He attributed these symptoms to overwork and irregular sleeping hours. He imbibed alcoholic beverages to a moderate degree. Several years before entry the patient had a penile lesion. The antisyphilitic therapy that followed was inadequate. He had had no recent antisyphilitic treatment.

On admission the temperature was 103.4°F., the pulse rate 100, the respiratory rate 26, and the blood pressure 124/68. The patient was well orientated and co-operative. He appeared to be acutely ill, and was drowsy. General physical examination revealed a well-nourished and well-developed colored man with a warm dry skin. The teeth were carious and the gums pyorrheic, but there was no lead line. The pharynx was moderately injected. The heart was of normal size, and there was a soft systolic apical murmur. Signs of consolidation of the lower lobe of the left lung were present. The remainder of the physical examination, including a careful neurologic survey, was essentially negative.

At 4 p.m. on the day of admission, sulfamethylthiazole therapy was initiated. The drug was administered orally in 60-gr. (4-gm.) doses every 4 hours, day and night. It was continued until 8 a.m. February 24, by which time the patient had received a total of 1680 gr. (112 gm.). Within 24 hours after admission the temperature had fallen to 99.2°F., and he appeared much improved. In the following 3 days, the patient continued afebrile, the cough abated and the chest findings indicated that the pneumonic process was undergoing satisfactory resolution. However, the patient was apathetic and drowsy. On the morning of February 24, he complained of vertigo and vomited several times, and sulfamethylthiazole was then discontinued. At 9 p.m., the patient vomited blood-tinged fluid projectily, there was profuse diaphoresis, and he complained of loss of vision. The blood pressure fell, and he became semicomatose. The pupils were widely dilated and reacted poorly to light. Fundus examination revealed fresh hemorrhages along the border of the superior temporal retinal artery of the right eye and in the macular regions of both eyes. On February 25 the patient was disorientated and irrational and still had amaurosis. There was no paralysis of the extremities, the tendon reflexes were normal, and no ab-

*This study was aided by a grant from the Charles E. Fleischmann Endowment.

†Fellow in neurology, Cincinnati General Hospital.

‡Assistant professor of neurology, University of Cincinnati College of Medicine; attending neurologist, Cincinnati General Hospital.

normal reflexes were elicited. At 1 p.m. on this day, 1 hour after a lumbar puncture was performed, the patient had a generalized convulsion, after which the right pupil was larger than the left, the right side of the mouth drooped, and the tendon reflexes on the right were hyperactive. The patient had two other generalized convulsions, lapsed in respiratory failure and died at 7 p.m. During the final 24 hours he was anuric.

The temperature varied from 103.6°F on the day of entry to 100.8 terminally. The pulse rate ranged from 60 to 100, and the respirations from 20 to 42. Sputum typing on admission revealed that the predominating organism was a Type 3 pneumococcus, no acid fast organisms were seen. Blood culture produced no growth. The blood Kahn reaction was positive. The blood sulfamethylthiazole levels were 10.8 mg per 100 cc on February 20, 13.3 mg on February 21 and 18.2 mg on February 22. On admission, the blood contained 12 gm of hemoglobin per 100 cc, and 3,700,000 red blood cells and 18,850 white blood cells per cubic millimeter. The differential count showed 80 per cent polymorphonuclear leukocytes, 16 per cent lymphocytes and 4 per cent monocytes. No stippling of the red blood cells was noted. The white cell count was normal by February 22, but on February 25 it rose to 12,800, with essentially the same differential picture noted above. The red cell count remained stationary. The urine contained a few white blood cells and a trace of albumin.

A lumbar puncture was performed on the afternoon of February 25. The initial pressure was not recorded, because the patient was extremely restless and could not be persuaded to relax. The cerebrospinal fluid was clear and colorless, and contained 15 lymphocytes per cubic millimeter and no red blood cells. The total protein content was 60 mg per 100 cc., the Wassermann reaction was negative.

Autopsy The autopsy was performed 15 hours after death. The pathological findings exclusive of those in the nervous system were resolving and organizing left lower lobe pneumonia, acute pleuritis, acute and chronic bronchitis with lobular pneumonia, chronic passive congestion of the lungs, healed tuberculosis of the hilar lymph nodes, chronic pulmonary emphysema, pin point hemorrhages in the subpericardium, the submucosa of the stomach and the submucosa of the urinary bladder, chronic active pericarditis, myocardial dilatation, atherosclerosis of the aorta and of the coronary and iliac arteries, toxic changes in the viscera with acute passive congestion, and chronic prostatitis. Post mortem blood cultures were negative. During the autopsy, portions of the brain, kidney and liver were removed, and analysis of their lead content made. As determined by the Kettering Laboratory (Dr Robert Kehoe), the lead levels in the brain were 0.35 mg per 100 gm of tissue, in the kidney 0.32 mg per 100 gm, and in the liver 1.75 mg per 100 gm. These values were considered unusually high and definitely abnormal.

Examination of the nervous system was limited to the brain, which weighed 1385 gm. The convolutions were moderately flattened and broadened, and the vessels of the meninges were markedly congested. The basilar meninges were slightly thickened. There was no obvious abnormality of the cranial nerves. The vessels of the circle of Willis contained scattered atheromatous plaques, and the circle was of normal configuration. There was a slight herniation of the uncus of the temporal lobe on both sides. There was a well defined cerebellar pressure cone.

The most notable feature of the brain, which was sec-

tioned 8 days after fixation in a 10 per cent solution of formaldehyde (USP), was the presence of discrete and confluent petechial hemorrhages scattered in the gray matter and nuclear structures (Fig 1). The tendency to symmetrical involvement was striking, and this symmetry was found wherever the vertical sections of the hemispheres and brain stem included comparable halves of the nervous system. The hemorrhages were bright red and tended to coalesce. Although these lesions were not profuse and extensive in the hemispheres, they were widespread, extending from the frontal to the occipital poles and sparing none of the lobes. The lesions were most marked in the tail of the caudate nucleus on both sides, where they measured 8 mm in diameter, and in the mammillary bodies. Smaller diapedetic hemorrhages were noted in the substantia nigra, thalamus and the gray matter of the convolutions. The white matter was entirely spared. The thalamus appeared swollen.

The sectioned brain stem showed a similar but much severer hemorrhagic lesion. Again the striking feature was the bilaterally symmetrical, coalescent, diapedetic hemorrhages involving the nuclear masses of the pons and medulla (Fig 2). The nuclei bordering on the floor of the fourth ventricle in the medulla and pons and the pontile and raphe nuclei were severely involved. The involved area on each side occupied approximately the dorsal fourth of the medulla. The lateral recesses of the fourth ventricle were filled with a soft clot, which obviously involved the choroid plexus. This hemorrhagic process extended into and destroyed a small portion of the adjacent cerebellar tissue on both sides. The remainders of the sectioned cerebellum, lower medulla and upper cervical cord were normal grossly.

Microscopic examination of various cortical areas and basal ganglia and representative portions of the brain stem confirmed the fact that the hemorrhagic process was limited strictly to the gray matter of these structures. Sections were stained by the hematoxylin and eosin, van Gieson, cresyl violet, Loyez, Bodian (1 per cent protargol) and benzidine (Lepehne-Pickworth) methods. The predominating lesion was diapedetic hemorrhage, which was widespread and consisted of discrete or confluent foci, in the center of each of which was a capillary or precapillary with hyperplastic or necrotic endothelium. Polymorphonuclear leukocytes were found in these hemorrhages and in the adjoining brain tissue. Blood pigment had diffused into the foci, and some of it had been ingested by macrophages. The hemorrhagic phenomena were most intense in the tail of the caudate nuclei, anterior nuclei of the thalamus, mammillary bodies and the paraventricular region of midbrain, pons and medulla. In the cerebellum, one small lobule, close to the midline and proximate to the brachia, was involved in the hemorrhagic softening (Fig 2). The entire lobule had partially lost its form, and there was some distribution of blood pigment throughout its gray and white matter. Here Purkinje cells were only rarely seen, and there was a marked loss of granular cells. The hemorrhage was diffuse and not limited to the area immediately surrounding the capillaries.

Besides these hemorrhagic lesions there were two other pathologic processes. In the gray matter of the cerebral hemispheres (cortex and basal nuclei) and brain stem there were a moderate number of discrete perivascular foci of necrosis. The center of each lesion contained a small capillary with necrotic or hyperplastic endothelium. Surrounding the vessel was a relatively acellular area that contained a few oligodendroglia and some so-called "ghost" nerve cells. These necrotic foci were usually de-

limited by a thin layer of neuroglial cells, one or two nuclei in thickness. The other characteristic lesions were areas of paling in the gray matter of the cortex, which were apparently not contiguous to the hemorrhagic or necrotic areas. These pale areas were relatively large

and neuronophagia were marked. In the superficial cortical layers, there were many polymorphonuclear leukocytes and microglia. In the cortical areas adjacent to the perivascular hemorrhage, there was also a moderate thinning of nerve cells, and the remaining cells showed

FIGURE 1. *Discrete and Confluent Petechial Hemorrhages Limited Macroscopically to the Cortex and Basal Ganglia.*

The cerebrum was sectioned vertically into blocks 1.5 cm. thick. Note the symmetrical arrangement of the lesions in the hemispheres (marked by arrows).

and contained swollen oligodendroglia and a few neurones, which showed severe anoxic changes.

The cortical architectonics in the areas containing the hemorrhagic lesions were markedly distorted. There was a notable absence of nerve cells, with an increase in neuroglia. Many ghost neurones were present. Sate

moderate to severe chromatolytic changes. The oligodendroglia of the gray and white matter was swollen and increased in amount. The leptomeninges, particularly over the sulci, contained generous amounts of polymorphonuclear leukocytes and lymphocytes in an exudate containing fibrin. There were also some large mononuclear

cells and a few phagocytes in the meninges. The vessels of the meninges were intensely congested.

An interesting neuronal change was noted in the hypothalamic nuclei, in which the nerve cells appeared to be most severely involved. They were markedly swollen, and there was an extrusion of Nissl granules from the cytoplasm of these cells into the surrounding tissue. The nuclei were absent. These hypothalamic cells appeared as though they had exploded. Satellitosis and neuronophagia were marked in this region.

There was marked congestion throughout the cerebral hemispheres and brain stem. This was noted in both the gray and white matter, particularly in the former. The capillaries and precapillaries showed severe changes, con-

associated perivascular foci of necrosis. Why one toxin should involve the white matter and the other the gray is not clear and needs further investigation.

The neuronal changes noted are evidently secondary to anoxia. Putnam and Alexander⁷ have pointed out that intermittent or isolated capillary closure in localized areas may produce no parenchymal degeneration, whereas closure of large areas of the capillary network, with consequent oxygen deprivation of the tissue, leads to necrosis.

FIGURE 2. Confluent Petechial Hemorrhages in the Nuclear Masses of the Pons and Medulla.

The symmetrical arrangement of the lesions is striking. The brain stem was sectioned vertically into blocks 1 cm thick. The cerebellum was split in the mid-line, and disarticulated from the brain stem by cuts through the brachia. A soft clot involved the choroid plexus of both lateral recesses and extended into adjacent lobules of the cerebellum.

sisting chiefly of swollen or necrotic endothelium. The hyperplastic endothelium frequently occluded the lumens of the vessels. There were numerous, thick thrombi. The perivascular spaces were accentuated. There was no perivascular cuffing or inflammatory cells, and no histologic evidence of syphilis.

The pathological findings in this case of hemorrhagic encephalopathy are of unusual interest because of the tendency for the hemorrhagic and necrotic phenomena to be confined to gray matter. This is in contradistinction to the typical arsphenamine hemorrhagic encephalitis, in which the white matter is the focal point of attack. However, these two morbid processes have several points in common. Both demonstrate, in addition to the diapedetic hemorrhage, widespread and severe vascular disorder in the gray or white matter, with

However, in pathologic processes in which there is a haphazard endothelial proliferation, there is only an intermediate degree of capillary closure. The end result of this latter state, as noted by Putnam and Alexander, is a rarefaction of cortical neurones comparable to that produced by other forms of incomplete or temporary anoxia, except that it is apt to be more patchy in distribution. In the hemorrhagic encephalitis induced by arsphenamine and sulfamethylthiazole, two pathologic processes manifest themselves simultaneously. The thrombotic capillary lesions lead to the focal areas of hemorrhage or perivascular necrosis, probably depending on the severity and speed of the process, and the varying degree of endothelial proliferation produces a disappearance of cortical

ganglion cells, usually of a patchy nature.

The presence of a high concentration of lead in the tissues of this case is of interest. It is doubtful, however, whether lead could produce the acute clinical and pathologic picture described here. Such a morbid process in an adult exposed to lead over a period of years has not been recorded in the literature. The administration of large quantities of sulfamethylthiazole, and the accumulation of this drug in the blood and tissues—owing, in part, to renal failure and closely associated with acutely developing signs of severe neurologic damage—are suggestive evidence that sulfamethylthiazole was the etiologic factor in the pathogenesis of the disorder in this patient.

SUMMARY

A fatal case of hemorrhagic encephalopathy is recorded, which occurred after the oral administration of sulfamethylthiazole. The pathological findings of greatest importance were focal peri-

vascular hemorrhages confined to the gray matter of the cerebral hemispheres and the nuclear structures of the brain stem. Focal perivascular areas of necrosis occurred, apparently simultaneously with the diapedetic hemorrhages. Profound alterations were noted in the small blood vessels, chiefly of the endothelium. Not infrequently these changes occluded the vessel. There was also severe, anoxic neuronal damage.

MEDICAL PROGRESS

THE VITAMINS*

ARNOLD P. MEIKLEJOHN, B.M. (OXON.)†

BOSTON

THE current literature on the vitamins continues to be voluminous. While remarkable progress is being made by biochemists in recognizing, identifying and finally isolating the various accessory food factors necessary for the health of animals, clinicians are equally industrious in applying the results of this work to the relief of human ailments. There can be no doubt that certain of the newly synthesized vitamins represent a very significant addition to the therapeutic armamentarium of the physician, but the medicinal value of some remains problematical. This is particularly true of those vitamins that have not yet been shown to be necessary for human health but are nevertheless recommended in the treatment of diseases in which there is at present no evidence to suggest a nutritional disorder.

In the following review, no attempt has been made to consider the greater part of the recent literature on the vitamins. Its scope is limited to contributions that are perhaps worthiest of the immediate attention of physicians.

VITAMIN A

Although vitamin A deficiency undoubtedly results in night blindness, there are still numerous difficulties involved in the use of dark-adaptation tests for the routine diagnosis of vitamin A subnutrition. Even though the technical problem of correctly measuring dark adaptation appears to have reached a satisfactory solution, there are still difficulties in interpreting the results obtained.¹ Poor dark adaptation is sometimes found in subjects with apparently adequate vitamin A intake; furthermore, the administration of vitamin A is not always immediately effective in the relief of partial night blindness. An explanation of such discrepancies is perhaps to be found in the recent report² of a study of experimental vitamin A deficiency. This study showed that although a rise in both rod and cone threshold is regularly obtained on a vitamin A deficient diet, there is nevertheless considerable individual variation in the length of time necessary to produce this change. Furthermore, when once impaired dark adaptation is established, it requires a variable but usually considerable time—often months—to restore the condition to normal by vitamin A therapy. The problem is further discussed in a paper³ that de-

scribes the occurrence of dermatitis characteristic of vitamin A deficiency in children living under poor economic circumstances in New York City. This study has an extensive bibliography, which should be found useful for those interested in vitamin A deficiency, and in the still unsolved problem of its incidence in the general population.

Methods for estimating vitamin A and carotene in blood are now available, but it is too early to say definitely whether they will eventually be useful for routine diagnostic purposes.

VITAMIN B COMPLEX

Thiamin

A most significant contribution to the study of deficiency disease in man is found in the results of experimentally induced thiamin⁴ and vitamin B complex^{5,6} deficiency reported during the year by two independent groups of workers. Hitherto, the only criterion for judging the clinical consequences resulting from deficiency of a given component of the vitamin B complex has been the therapeutic test of administering this component to clinical cases of deficiency disease and observing the extent of the therapeutic response. Such tests are frequently difficult to interpret, since despite the most careful precautions, some of the observed response may be due to nursing care (in pellagrous dermatitis), bed rest (in beriberi heart disease), or even other factors in the diet. The experimental production of such deficiencies under carefully controlled conditions is therefore a most valuable step in helping to define clearly the specific clinical features that result from lack of individual dietary factors.

The study⁴ of induced thiamin deficiency was carried out on 4 female subjects who were fed a basal diet, extremely low in thiamin, but supplemented with adequate amounts of other vitamins. Two other subjects served as controls, and received in addition to the diet varying amounts of synthetic thiamin chloride. The diet was continued for eighty-eight days, after which it had to be terminated owing to uncontrollable nausea and vomiting. The symptoms of which the experimental subjects complained included: fatigue, lassitude, backache, insomnia, muscular weakness and tenderness, extreme anorexia, nausea, vomiting, constipation, loss of weight, palpitation, dizziness, dyspnea and precordial distress. The objective manifestations of the deficiency included: a fall in work capacity, low blood pressure, faint heart sounds and bradycardia at rest, with tachycardia and sinus arrhythmia on exertion. Laboratory investigations showed electrocardiographic changes, —decrease in amplitude with occasional inverted

T waves,—sugar curves of diabetic type, and an increase in the concentration of lactic acid and bisulfite-binding substances in the blood, particularly after exercise. None of the subjects developed edema, cheilosis, glossitis, dermatitis or anemia. There was no fall in serum proteins, and the heart size remained normal throughout. In 2 cases there was absolutely no evidence of peripheral nerve changes; of the others, one developed depressed tendon reflexes, and the other paresthesias of the feet, but apparently only late in the deficiency when vomiting was severe and the absorption of other dietary factors besides thiamin probably reduced in consequence. The foregoing abnormalities, without exception, were completely cured by the administration of synthetic thiamin hydrochloride, while the diet was continued unchanged.

In the other study,^{5,6} use was made of a somewhat different procedure. A female volunteer subject was fed a diet that was deficient in the entire vitamin B complex. The diet was continued for nine weeks, after which thiamin, then riboflavin and finally whole yeast were successively added to the diet, and the improvement due to each observed. The abnormalities noted included almost all those observed in the study previously mentioned, but in addition the subject developed edema,—without, however, any alteration in serum-protein concentration,—macrocytic anemia and x-ray evidence of disturbed gastrointestinal motility, as shown by increased caliber in the loops of the jejunum and delay in the passage of the meal. Synthetic thiamin hydrochloride completely relieved the dyspnea, precordial distress, variable pulse rate, nausea, vomiting and muscle and nerve tenderness. Certain manifestations were only partly or temporarily relieved by thiamin, including anorexia, weight loss, extreme fatigue, loss of memory and inability to concentrate. The anemia, edema and gastrointestinal disturbance were uninfluenced by thiamin or riboflavin but responded to the administration of whole yeast. As in the former study, there was evidence of a disturbance of carbohydrate metabolism, as shown by a diabetic type of sugar curve, which, however, was restored to normal not by thiamin but by whole yeast. The ingestion of glucose was also accompanied by a rise in blood lactic and pyruvic acids; this abnormality was corrected by thiamin alone. The only changes that might be interpreted as evidence of early polyneuritis were a decrease in electrical irritability, muscle and nerve tenderness and unilateral facial hypesthesia.

One striking feature of both studies is the absence of any clear evidence of polyneuritis resulting from deficiency of thiamin. This is in agree-

ment with the conclusions reached from a recent study⁷ of the literature. As this study shows, the belief that thiamin lack results in polyneuritis is founded on a misconception. The only certain consequence of this deficiency is a disturbance of carbohydrate metabolism, resulting in the accumulation of lactic and pyruvic acids in the tissues. This disturbance in animals causes certain neurologic signs, and in man, muscular pain and weakness. The relief of these changes by the administration of thiamin has given rise to the erroneous belief that thiamin will cure nutritional polyneuritis, which frequently coexists but is due to another, probably multiple, deficiency. In view of this and of the foregoing evidence it appears that thiamin should no longer be referred to as the antineuritic vitamin. It is of interest that recent experiments⁸ on pigs have produced extensive degenerative changes in both the central and peripheral nervous systems by feeding a diet adequate in thiamin, riboflavin and nicotinic acid but lacking some unknown factor or factors present in yeast and liver.

Another interesting feature of the foregoing experimental studies is the clear demonstration of the disturbance of carbohydrate metabolism that results from thiamin deficiency, as evidenced by changes in the blood levels of sugar and lactic and pyruvic acids, detectable under suitable conditions. This change in metabolism is presumably responsible for at least the greater part of the clinical findings in these subjects; and as might be expected, they are not easily distinguished from those resulting from any other influence affecting adversely the normal, healthy, biochemical processes of the body. The clinical picture is that of general ill health, both physical and mental. From a practical point of view it is clearly difficult to distinguish thiamin deficiency, except perhaps in its extreme forms, on clinical grounds alone. For this reason there is a definite need for some reliable laboratory test for this deficiency. The estimation in blood of thiamin and of its pyrophosphate cocarboxylase has been accomplished,⁹ but the available methods are too elaborate for routine clinical use, and furthermore, since low values have been obtained in a curious variety of clinical conditions, it is difficult at the present time to assess the significance of such values in terms of actual lack of thiamin. It is now a relatively simple matter to estimate thiamin in urine; but here again there are difficulties in the practical interpretation of the values so obtained. Apparently the excretion of thiamin "varies so rapidly with the intake that it reflects to a large extent the diet during the day or two

preceding the time of urinary excretion."¹⁰ A low excretion level is therefore not necessarily indicative of inadequate nutrition in regard to this vitamin. It is possible, however, that some procedure based on a test-dose method may ultimately yield results of practical diagnostic value.

Riboflavin

One important advance in nutritional therapy has been the report by two independent groups of workers of the relief by riboflavin of a certain disorder of the eyes. It had been reported¹¹ that rats fed on a diet deficient in riboflavin developed an unusual vascularization of the cornea, which was relieved by the administration of this vitamin. However, no similar lesion in man had been attributed to nutritional deficiency until the report,¹² published during the last year, that vascularization of the cornea occurs in malnourished subjects in the South, and that riboflavin is usually effective in its relief. Shortly afterward it was reported¹³ that the lesion formerly known as acne rosacea keratitis usually responded to treatment with riboflavin. This is of particular interest, since acne rosacea has long been suspected of being a manifestation of nutritional deficiency. However, the associated skin lesions usually respond less well to the administration of pure riboflavin. In its severest form the full ocular syndrome attributed to riboflavin deficiency includes: circumcorneal injection, vascularization of the cornea, corneal ulceration and opacities, dim vision, photophobia, mydriasis, iritis and pigmentation of the iris. The explanation of these manifestations is apparently to be found in the peculiar characteristics of the cornea, which, lacking any vascular supply, is unusually dependent for its normal metabolism on the activity of Warburg's "yellow enzyme," an important respiratory enzyme of which riboflavin is an essential constituent. Furthermore, since riboflavin may be inactivated by light, the constant exposure of the cornea may render it peculiarly susceptible to depletion of the yellow enzyme unless a new supply of riboflavin is constantly provided by the diet. It has not as yet been adequately demonstrated how frequently the foregoing syndrome may arise from causes other than riboflavin deficiency, and the fact that it is frequently curable with synthetic riboflavin does not imply that this is the most economical and effective form of treatment. Extracts of yeast or liver are rich in riboflavin and very much cheaper than the synthetic material. Moreover, they may be more therapeutically effective, since they supply other factors that have curative value for associated deficiencies.

As mentioned in last year's review¹⁴ the clinical

manifestations of angular stomatitis and cheilosis, although undoubtedly curable by riboflavin in certain cases, are more likely to be a general manifestation of poor nutrition, however caused. In support of this view is the report¹⁶ that cheilosis has been relieved by the administration of pyridoxin (vitamin B₆).

Other Components of the Vitamin B Complex

Two new components of the vitamin B complex have now passed the stage of chemical identification and synthesis, namely pyridoxin (vitamin B₆) and pantothenic acid (filtrate factor). These vitamins have been recognized and identified by the fact that they are necessary for the maintenance of health in animals. The peculiar situation has arisen that they are now available for clinical trial in synthetic form before it is known whether they are necessary for normal health in man. Already there are reports that pyridoxin is valuable in the relief of epilepsy, muscular dystrophy, Parkinsonism and certain symptoms of pellagra, but in my opinion such reports should be treated with circumspection until further evidence is forthcoming. An initial trial of pyridoxin in cases of nutritional deficiency was disappointing,¹⁰ and at present there appears to be no definite evidence that pantothenic acid is a necessary constituent of the human diet.

ASCORBIC ACID (VITAMIN C)

As with thiamin, so with ascorbic acid, a very material advance has been achieved in the past year by the publication¹⁷ of a careful study of experimentally induced human ascorbic acid deficiency. As a result of this study a number of traditional beliefs regarding clinical scurvy require some revision. A young male adult placed himself on a diet lacking in vitamin C, supplemented with other known vitamins, for a period of six months. The first interesting feature was the remarkably long latent period required before any hemorrhagic manifestations developed; perifollicular hemorrhages were first observed after the diet had been taken for one hundred and sixty-one days. This is considerably longer than the time that was formerly thought to be necessary for the induction of scurvy, and gives rise to the suspicion that in clinical scurvy, as ordinarily observed, other deficiencies may contribute to hasten and exaggerate the effects of ascorbic acid deprivation. The earliest clinical evidence of the deficiency was the appearance over the lower extremities of hyperkeratotic papules containing ingrown hairs. Such papules have been previously observed in scurvy, but hitherto they have usually been regarded as evidence of coexisting vita-

min A deficiency. It is therefore a matter of some interest that they can result from ascorbic acid deficiency alone. The level of ascorbic acid in the blood plasma fell to zero early in the experiment, yet following this, thirteen weeks elapsed before any signs of scurvy developed. This provides further evidence that the estimation of ascorbic acid in plasma gives little information about the presence or imminence of clinical scurvy. However, this study confirmed the reported diagnostic value of estimating the level of ascorbic acid in the platelet-white-cell layer of centrifuged blood.¹⁸ This level did not fall to zero until shortly before the onset of hemorrhagic manifestations. It was of further interest that no anemia developed in the course of the deficiency, in spite of considerable blood loss through venesection. This is in agreement with recent observations,¹⁹ which indicate that the anemia often associated with clinical scurvy may be due to some deficiency other than that of vitamin C. Another negative finding was the absence of changes in the gums, perhaps because of pre-existing good oral hygiene. Two surgical wounds were made during the course of the experiment. The first—after the deficient diet had been taken for three months—healed normally, despite the fact that the level of ascorbic acid in the plasma had been zero for forty-four days. The second wound, made at the end of six months, failed to heal until ascorbic acid was administered. These results suggest that defective wound healing on the basis of ascorbic acid deficiency is unlikely to occur except when the deficiency is severe.

VITAMIN E

Vitamin E is another vitamin that is now available in purified form (synthetic alpha-tocopherol) before it is known for certain whether it is essential for normal nutrition in man. It is certainly necessary for certain animals in which its deficiency produces a degeneration of the spinal cord and associated muscular atrophy. In view of this it has been recommended in the treatment of amyotrophic lateral sclerosis in man, but the initial results of its use in human neuromuscular disorders appear to be disappointing.²⁰

VITAMIN K

The first clinical reports of the value of vitamin K, discussed in last year's review,¹⁴ have been amply confirmed by numerous publications in the last twelve months. The literature is now so extensive that it is beyond the scope of a short review of this kind. For recent summaries, the reader is referred elsewhere.^{21, 22} The beneficial

results of vitamin K administration in hemorrhagic disease of the newborn²³ and in hypoprothrombinemia associated with diseases of the biliary tract,²⁴ especially when surgery is contemplated,²⁵ have been further emphasized. It has been pointed out that a grave prognosis is to be expected when vitamin K administration fails to raise the blood prothrombin concentration in cases of liver disease with hypoprothrombinemia.²⁶

A method has been published²⁷ whereby stable thromboplastin may be prepared, and when this material becomes generally available, Quick's prothrombin test should become a routine procedure in every clinical laboratory. Despite reports of simpler methods for estimating prothrombin concentration, this test continues to be the most reliable for clinical purposes. Another practical achievement has been the production of a water-soluble form of synthetic vitamin K that can be administered parenterally. This is particularly valuable when a rapid response is desirable, as in surgical cases of obstructive jaundice with hemorrhage.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27101

PRESENTATION OF CASE

A fifty-four-year-old woman entered the hospital complaining of vaginal bleeding.

The patient was first seen in the Out-Patient Department four years before admission, at which time she stated that although her periods were regular there was an increase in menstrual flow and a lengthening of its duration from five to ten days, with accompanying hot flashes. A dilatation and curettage was performed and showed normal endometrium in the early secretory phase. During the next year her periods were normal, but the hot flashes continued. Two years before admission menorrhagia again appeared, and the periods lengthened to ten days, although they were still regular. In addition, the patient suffered from morning nausea, — occasionally with vomiting, — frequent headaches, insomnia and nervousness. There had been no weight loss, and physical examination was negative. These symptoms lasted for a year and a half, when menstruation ceased for three months, but at the end of this time an excessive flow occurred, lasting for one month. This was followed a month later by an apparently normal period, and then amenorrhea with disappearance of the hot flashes and other symptoms. No further bleeding occurred until one month before admission, when the patient noticed a slight spotting and found it necessary to use one pad daily. She noticed also that the same sensation arose in her breasts that she was accustomed to associate with menstruation. Nine days before admission the flow suddenly increased to a point necessitating twelve pads daily. The patient said that "the blood seemed to gush out." This was accompanied by anorexia and intermittent crampy lower abdominal pain aggravated by standing and walking. These symptoms abated somewhat two days before admission. The patient stated that she had lost 5 pounds in nine days. She had had seven pregnancies — five children and two miscarriages.

The family history was irrelevant. The patient had had a dilatation and curettage after her second miscarriage twenty-three years before admission.

On examination the patient was well developed and well nourished and in no distress. Examination

of the heart and lungs was negative; the blood pressure was 125 systolic, 90 diastolic. The abdomen was found to be tender in its entire lower portion, most marked in the right lower quadrant, but no masses could be felt. On pelvic examination, hemorrhoids were present and the perineum was relaxed. The cervix was small, soft and non-tender, and showed a well-healed laceration and a bloody discharge. One examiner believed that there was definite resistance to palpation in the left vault, with a clear right vault. The fundus was slightly enlarged, but in normal position. Examination of the nervous system was negative.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. Examination of the blood showed a red-cell count of 4,000,000 with a hemoglobin of 68 per cent, and a white-cell count of 10,100. A blood Hinton reaction was negative. Culture of the cervix was negative for beta hemolytic streptococci.

On the second hospital day an examination under ether anesthesia revealed the fundus to be about twice normal size, but freely movable; the vaults were clear. An operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JUDSON A. SMITH: The history of this bleeding is a little confusing. The story begins four years before admission, and appears to be only the history of a woman with some menorrhagia and the symptoms of the menopause. I think we can ignore that part of the history. Two years before admission, the menorrhagia again appeared and the periods lengthened, a condition that lasted a year and a half, which brings this story up to six months before admission. That also does not seem to have any bearing on the present condition. Let us start there and note that six months before admission the patient missed a period for the first time except for her pregnancies. She missed three periods, and after that had a month of fairly profuse bleeding, but we are not told whether she had cramps or signs of abortion. A month later she had what was apparently a normal period. It is important to consider that it might not have been a normal period but a spell of bleeding that passed for a period. Then she had amenorrhea for an indefinite period, which could not have been long. If we knew how long, it might be of some help in figuring out this case. Finally, she was admitted with a story of profuse bleeding for the nine days preceding admission.

When she was examined, the only positive finding was tenderness in the lower abdomen and enlargement of the uterus, with a soft cervix from

which there was a bloody discharge. It is impossible to make a diagnosis on a case like this without a curettage. There are two essential procedures: one is the examination under anesthesia, which was done and which presumably showed only that the uterus was twice normal size. I suppose that we can presume that it was smooth and normal in shape and not softer or harder than the ordinary uterus. The other essential procedure is a curettage.

If we try to make a diagnosis without the results of curettage, I think the reasoning goes like this: There are three categories, into one of which this case must fall: functional bleeding, neoplasm and some complication of pregnancy. Let us take functional bleeding first. The diagnosis of functional bleeding can be made only after other diagnoses have been excluded by curettage. However, the enlarged uterus and the crampy pain with tenderness do not fit well with functional bleeding. In addition, no one felt a mass that could be a tumor or cyst of the ovary. When we come to the question of neoplasm, we have to consider in any patient bleeding at this age the possibility of cancer of the fundus, which can be excluded only by diagnostic curettage. I get the impression from the story, however, that the bleeding was more acute and profuse than one would naturally associate with cancer of the fundus. So far as bleeding from fibroids is concerned, we have the fact that under ether no one felt them in the uterus; if the patient had them, they must have been submucosal. We are left with the possible complications of pregnancy, among which there is also neoplasm, of course, namely, a chorion-epithelioma.

One can construct two or three plausible hypotheses to explain this bleeding, starting with the assumption that the patient was pregnant. In the first place, if she had been admitted to the hospital and nothing had been known about the past history, nine days of profuse bleeding, crampy lower abdominal pain and a uterus twice normal size would suggest that she was in the process of aborting. For obvious reasons, that does not seem impossible in this case, even though the patient is fifty-four years old. We could then explain the rest of the history, of course, by saying that the previous amenorrhea was the onset of the menopause, or we might go back farther and suppose that she became pregnant at the time the amenorrhea started, skipped three periods, had a blighted ovum, and then had a month's flowing and aborted herself without realizing that she had been pregnant. In that case she might be bleeding now because of retained products of conception, from what we call a placental polyp or from a chorion-epithelioma. If that were so, she ought to have

a strongly positive Aschheim-Zondek reaction. Is there a report of an Aschheim-Zondek test?

DR. TRACY B. MALLORY: None was done.

DR. SMITH: I suspect that the examiners did not consider the possibility that the patient was pregnant, and perhaps she was not. The third hypothesis, which is perhaps the most attractive of all, is what is called a "missed abortion." Because the patient was menstruating regularly, we assume that she was still fertile, that she became pregnant, and that the fetus died without any signs of abortion. Then later she bled profusely, possibly had cramps but still did not abort; she went on another month, had another spell of bleeding, loss of appetite, loss of weight, a large uterus and crampy lower abdominal pain. That would, I think, perfectly explain everything, and to my mind is the most plausible diagnosis, although without a curettage, it is more a guess than a diagnosis.

CLINICAL DIAGNOSIS

Functional bleeding?

Carcinoma of the fundus?

DR. SMITH'S DIAGNOSIS

Missed abortion.

ANATOMIC DIAGNOSES

Follicular cyst of ovary.

Proliferative endometrium.

"Functional bleeding."

PATHOLOGICAL DISCUSSION

DR. MALLORY: After the ether examination, the house staff proceeded with a diagnostic curettage. This showed a grossly normal endometrium, and frozen sections likewise showed no histologic evidence of cancer. For reasons that were not anatomically apparent, the surgeon decided to perform a complete hysterectomy; we consequently had the opportunity to examine the uterus and ovaries in detail, and they were all absolutely negative except for a follicular cyst in one ovary, so that this case must be classified as functional bleeding at the menopause, and we can safely rule out anything else.

DR. GEORGE A. MARKS: Was there proliferative or hyperplastic endometrium?

DR. MALLORY: There was a proliferative endometrium, with an occasional dilated gland, but the whole thickness of endometrium was barely over a millimeter, so that we could hardly call it hyperplastic.

DR. JOE V. MEIGS: The follicular cyst is characteristic. If the patient had an ovarian cyst and amenorrhea, followed by bleeding, she probably had metropathia hemorrhagica, a condition that I should have thought of first, not being an obstetrician.

CASE 27102

PRESENTATION OF CASE

A sixty-three-year-old Italian housewife entered the hospital complaining of vaginal bleeding.

The patient's menopause occurred at the age of forty, and she had had no bleeding since that time, until five weeks before admission when, during urination, she noticed a few drops of blood, which appeared to be coming from her vagina. This occurred on two other occasions, but at no time were her clothes stained. Two days before admission, while at stool, about "a quarter of a wine glass" of blood escaped from her vagina. The patient had not lost weight, nor had she noticed any blood in her stools, change in bowel habits, pain or urinary symptoms. She had had twelve children and three abortions.

For the previous twenty-five years the patient had been treated for diabetes mellitus without insulin, and for a little more than a year she had been treated in this hospital for arteriosclerotic heart disease with hypertension and paroxysmal tachycardia. The family history was irrelevant.

On examination the patient was well developed, obese and in no apparent discomfort. The heart was slightly enlarged to percussion, and a loud high-pitched systolic murmur could be heard in the aortic area, which was transmitted into the neck vessels. The rhythm was regular, the aortic second sound greater than the pulmonary second, the blood pressure 150 systolic, 80 diastolic. Examination of the lungs revealed moist rales at each base posteriorly. Examination of the abdomen and extremities was negative. On vaginal examination the perineum was relaxed, with a moderate cystocele and rectocele. There was a slight reddening of the urethral orifice. On the posterolateral wall of the vagina there was a firm 0.5-cm. nodule, the color of which blended with that of the mucosa. Another 0.3-cm. nodule was present on the anterior wall in front of the cervix. The cervix was of normal size, smooth and freely movable. The vaults were clear; the fundus could not be felt.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. Examination of the blood showed a red-cell count of 3,980,000 with a hemoglobin of 80 per cent, and a white-cell count of 8400. A blood Hinton reaction was negative.

On the fourth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. WARD L. GREGG: Apparently this was a mild diabetic patient with arteriosclerotic heart disease

not completely compensated, who gave a short story of intermittent, painless mild postmenopausal bleeding. The chief probable causes for painless postmenopausal bleeding twenty-three years after the cessation of the last period are: carcinoma of the fundus, atrophic vaginitis, carcinoma of the cervix, cervical polyps, uterine polyps, carcinoma of the tube and neoplasm of the ovary, such as granulosa-cell tumor. One must also consider idiopathic fundal or cervical bleeding, so-called "uterine apoplexy," probably owing to some vascular breakdown in the cervix or uterus, not connected with any recognizable disease entity in the genital tract. Moreover, a calcified submucous or intramural fibroid can bleed before or after the menopause as the result of breakdown of the tissue owing to pressure. Finally, a neoplastic lesion primary in the vagina itself is possible.

This obese woman was apparently not anemic and showed no weight loss, which would rule out any very extensive process. Vaginal examination showed a relaxed pelvic floor, with cystocele and rectocele, which is not surprising after so many pregnancies. It is not remarkable for even a mild diabetic patient to have a reddened urethral orifice. There is no mention of vaginal reddening to suggest an atrophic vaginitis with secondary fundal infection, which is rather uncommon but oftener seen in diabetes. There are described, however, two small, firm discrete nodules in the vaginal mucosa without discoloration of the overlying mucous membrane or evidence of recent ulceration that might cause bleeding. Since there is no ulceration, I am going to assume that the bleeding did not come from the nodules, but that they might well have represented metastases. The cervix was normal in size, smoothness and mobility, and no cervical polyps or erosion was described. The fundus could not be palpated because of obesity. There is no mention of a Clark test; this consists in the passage of a uterine sound through the cervix, a procedure which, if a friable lesion is present in the uterus, produces bright bleeding on withdrawal of the sound.

Calcified myomas are rarely seen and easily diagnosed with either curettage or the passage of a uterine sound. Neither carcinoma of the tube or ovary, uterine polyp, idiopathic bleeding nor atrophic vaginitis could account for the vaginal nodules if we assume that they were metastatic in origin. It is conceivable that carcinoma of the tube or ovary could produce metastases in the vagina, but this would be rather rare—less than 0.5 per cent. The usual channels from tube and ovary are to the peritoneum, pleura, lung, heart, spleen and bone, in more or less that order. Another thing that points against carcinoma of the

the problems of cause and effect that these most prevalent and disabling diseases present to both clinicians and research workers. One hundred and thirty physicians are members of this council.

The report details the work of the council from November, 1939, to November, 1940. No one can read this stimulating brochure dealing with "The Defence Forces," "Research," "Administration" and "The Future" without agreeing with the statement, "During twelve months of resistance to the Nazi attempt to plunge the world again into a Dark Age, the full brunt of which has fallen on these islands, the decision of 1939, that our council should carry on with its work, has been justified."

In the face of great difficulties and grave dangers the research projects that had already been undertaken were continued until almost the close of the year. One of the laboratories was hit by a bomb and the building seriously damaged. Special hospitals for the treatment of rheumatic diseases are being planned for the army, since the very considerable incidence of these diseases among the soldiers in World War I is likely to be still greater because the conditions of service in highly mechanized warfare make soldiers more susceptible to them. Lord Horder has accepted the chairmanship of the Medical Advisory Committee of the Ministry of Labor and of the Committee of Inquiry Regarding Health Conditions in Air-Raid Shelters, and the council is thus in close touch with these key positions in relation to the war on rheumatic diseases. The receipts and payments of the council account to October 31, 1940, seem to show a favorable balance of over £6000.

In time of peace the Empire Rheumatism Council prepared for war and for the control of a group of chronic diseases that they knew would follow. Now in war they are striving to lessen the load of disability that must be carried long after peace is declared, by attacking these chronic diseases as soon as the early signs appear.

This outstanding effort should stir our country to do likewise. The American Rheumatism Association has appointed a committee to deal with

the problems of military defense. This committee has offered its services to the proper officials of the United States Army and to various committees of physicians concerned with national defense, in relation to the organization of special courses in the treatment of arthritis and to making personnel available. It is hoped that such services will eventually be accepted, for in times of even possible war it is surely not too early to prepare for one of the greatest problems that peace presents. In this regard, it is well to note the last paragraph of Lord Horder's report:

We can, I feel, look back on the work of the past four years—work tragically hindered by war and preparations for war—with some satisfaction. Research into causative factors has progressed. Clinical research into methods of treatment has made notable advances. We are far better equipped than we were in 1936 to advise the community as to how the ravages of rheumatic diseases can be checked at once, and have made distinct advance towards the objective of effective control. Such effective control, when it comes to be realized, will remove from humanity one of its greatest afflictions, bringing us nearer to understand the vision of Isaiah: "They shall not hurt nor destroy in all my holy mountain, for the earth shall be full of the knowledge of the Lord, as the waters cover the sea."

MEDICAL EPONYM

GROCCO'S TRIANGLE

Pietro Grocco (1857-1916), of Florence, first described his triangle at the fourth session of the twelfth congress of the Società Italiana di Medicina Interna, in October, 1902. An abstract of his remarks appears under the title "Triangolo paravertebrale opposto nella pleurite essudativa [The Paravertebral Triangle on the Side Opposite to Pleurisy with Effusion]" in the transactions of the society: *Lavori dei Congressi di Medicina Interna* (12: 190, 1902). A portion of the translation follows:

Professor Grocco thus designates a new symptom, which he has often found in pleurisy with effusion. It consists in a triangular area of relative dullness on the posterior wall of the thorax opposite the side involved. The internal border of this triangle is represented by the line of the spinous processes, the base by the lower limit of thoracic resonance (which varies somewhat over a space of 3 to 6 cm.), and the external border by a line that extends obliquely upward to the highest point reached by the level of the exudate.

Over this area the impairment of sound is more marked toward the median line and toward the base, and the base line itself varies in length and degree of dullness with different positions of the patient as he lies in bed, and with variations in the amount of fluid. The fluoroscope and radiogram confirm the percussion findings. This is illustrated by the accompanying figure, which shows two radiograms, one taken during life, the other from a cadaver in which one pleural cavity was filled with a solution of lead acetate. The test on the cadaver tends to support the idea that the pleural sac, when full of fluid, extends beyond the median line sufficiently and in such a way as to explain the triangular area of dullness above mentioned.

RHEUMATIC HEART DISEASE IN PREGNANCY

Mrs. E. G., a twenty-seven-year-old para III at term, entered the hospital on March 28, 1940, complaining of irregular abdominal cramps, shortness of breath and swelling of the ankles.

The family history was noncontributory. At the age of ten the patient had rheumatic fever with involvement of the heart. The tonsils and adenoids were removed at that time. When the patient was sixteen and again when she was twenty, the rheumatic fever recurred with slight heart involvement. There were no signs or symptoms of decompensation. Catamenia began at thirteen, were regular with a twenty-nine day cycle and lasted five days. The last menstrual period began on July 8, 1939, making the expected date of confinement April 15. The first pregnancy ended in a stillbirth following a placenta previa in 1932, the second was a full term normal delivery in 1936. There were no cardiac or other complications during these pregnancies.

The patient was first seen in the prenatal clinic on November 2, 1939, and was instructed to return weekly. She did not exhibit any untoward signs or symptoms obstetrically or medically. Her last visit to the clinic was on February 29, and she was not seen again until she entered the hospital.

Examination at the time of admission revealed cyanosis of the lips, dyspnea to the point of or-

thopnea, and considerable edema of the lower extremities. There was enlargement of the heart to the left and downward, and a presystolic and systolic murmur at the mitral area, with transmission to the axilla. The rate was 125, and the rhythm regular. The blood pressure was 160 systolic, 110 diastolic. The respirations were 26, and there were many fine moist rales at both lung bases. The liver edge was palpable two fingerbreadths below the costal margin. The fundus was four fingerbreadths below the xiphoid, and the fetal heart was audible in the left lower quadrant. Rectal examination showed the cervix thick, not taken up and dilated to admit one finger. A consultation was held with a cardiologist, who reported: "The heart is enlarged to the left, the rhythm regular, the rate increased. There is a double mitral murmur. Mitral stenosis is the dominant lesion. The lungs are moist at both bases. Diagnosis: rheumatic heart disease (double mitral) and beginning decompensation. Recommend digitalization, moderate restriction of fluids, a 1200 calorie diet and $\frac{1}{2}$ gr. morphine sulfate every four or five hours as necessary."

The patient started in active labor at 10 p.m. on March 28, and after labor was well established, she was given 3 gr. Nembutal. Nitrous oxide and oxygen were administered during the second stage and during delivery, which resulted in a living male child.

Obstetrically the patient had an uneventful postpartum course. Following delivery, respiratory distress was slightly relieved, but dyspnea continued while the patient was in a recumbent position. The edema gradually disappeared, and the urinary output increased. Ten days postpartum the moisture at the lower lung field had cleared, and the edema had entirely disappeared. The patient's general condition was greatly improved, and her only complaint was shortness of breath when lying down. She received ammonium chloride and $\frac{1}{2}$ gr. digitalis daily. In view of the improvement and the absence of any signs of cardiac decompensation, the patient was permitted to sit up on April 19, three weeks postpartum. However, almost immediately edema of the extremities reappeared, and absolute bed rest was again necessary. The temperature continued to remain normal, the pulse was regular, and the respirations were normal. The blood pressure ranged from 160 to 140 systolic, and 100 to 60 diastolic. The urinary output again closely paralleled the intake, the edema cleared, and the patient appeared greatly improved. On May 10 she was allowed out of bed, and continued to be ambulatory until her discharge on May 18.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Comment. This case illustrates that rheumatic heart disease must always be considered a potentially serious complication during pregnancy. Previous pregnancies without decompensation do not necessarily mean that the individual heart is able to carry on successfully in subsequent pregnancies. This patient gave no history of decompensation following the attacks of rheumatic fever or during two previous full-term pregnancies. Furthermore, there was no apparent decompensation until approximately the stage of pregnancy at which the load is supposed to diminish. The patient went through her labor successfully, in spite of existing signs of decompensation. That the heart muscle had been definitely damaged was shown by the history of recurring signs of cardiac failure when the patient was first allowed to get out of bed. This heart should never again be asked to stand the load of pregnancy; if pregnancy should take place, interruption should be considered.

VETERANS' INFORMATION ON DEATH CERTIFICATES

In the June 13, 1940, issue of the *Journal*, attention was called to the failure of many physicians to list on death certificates the status of the deceased as a veteran, as required by Sections 9 and 10 of Chapter 46 of the General Laws.

The standard death certificate has recently been revised by Arthur J. Hassett, registrar of vital statistics. These new certificates are ready for use, and in their present form there is even less excuse for the attending physician to fail in making a complete record.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 9:

BERKSHIRE

Thursday, March 13, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. Surgery of the Hand. Instructor: Franklin G. Balch, Jr. Harry G. Mellen, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday, March 11, at 4:30 p.m., at the Union Hospital, Fall River. Diagnosis, Treatment and Prognosis of Central-Nervous-System Syphilis. Instructor: Francis M. Thurmon. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday, March 13, at 8:00 p.m., in the Library of the Franklin County Public Hospital, Greenfield. Pediatric Case Discussions. Instructor: Louis K. Diamond. Halbert G. Stetson, *Chairman*.

HAMPDEN

Wednesday, March 12, at 4:00 p.m., at the Academy of Medicine, Professional Building, 20 Maple

Street, Springfield, and at 8:00 p.m., in the Out-patient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Obstetric Complications with Case Histories and Clinical Problems. Instructor: Meinolf V. Kappius. Alfonso A. Palermo, *Chairman*.

HAMPSHIRE

Thursday, March 13, at 4:15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Dermatitis and Eczema. Instructor: Bernard Appel. Robert C. Byrne, *Chairman*.

WORCESTER

Tuesday, March 11, at 8:30 p.m., in the Nurses' Home of the Milford Hospital, Milford. The Treatment of Varicose Veins. Instructor: Robert R. Linton. Joseph Ashkins, *Chairman*.

WORCESTER NORTH

Friday, March 14, at 4:30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg. Therapeutic Uses of Preparations of Endocrine Glands: Thyroid gland, pituitary gland, ovary, testis and adrenal cortex. Instructor: William T. Salter. George P. Keaveny, *Chairman*.

DEATH

BRIGGS—L. VERNON BRIGGS, M.D., of Boston, died at his winter home at Tucson, Arizona, February 28. He was in his seventy-ninth year.

Born in Boston, he attended Boston Latin and Chauncy Hall schools, passing entrance examinations for Harvard Medical School at the age of fifteen. Although too young to be enrolled at the school he was allowed to attend lectures there. After a voyage around Cape Horn, for his health, he went to Honolulu, where he studied under Dr. John S. McGrew. A year later he returned to this country, studied in San Francisco and also at Tufts College Medical School and Dartmouth Medical School. He finally received his degree from the Medical College of Virginia in 1899, and started the practice of psychiatry in Boston.

Dr. Briggs then became the associate of Dr. Walter Channing at his Brookline sanitarium. He soon opened his own sanitariums, which were the first in the country to admit curable mental patients only. While secretary to the state board of insanity he did much to improve the care of the mentally ill in Massachusetts.

He held fellowships in numerous societies, among which were the Massachusetts Medical Society and the American Medical Association, the American Psychiatric Association and the New England Society for Psychiatry.

His widow and a son survive him.

MISCELLANY

NOTES

Dr. Francis G. Blake, Sterling Professor of Medicine, has been appointed dean of the Yale University School of Medicine.

Dr. William T. Salter, assistant professor of medicine, Harvard Medical School, associate physician, Thorndike Memorial Laboratory, and junior visiting physician, Boston City Hospital, has been appointed professor of pharmacology, Yale University School of Medicine.

Dr Merrill Moore has been appointed to serve as medical director of the Washingtonian Hospital

On January 24, Dr William B. Castle gave the Edward Gamaliel Janeway Lecture at Mount Sinai Hospital, New York City, his subject being "Hemolytic Anemias"

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JANUARY, 1941

DISEASES	JANUARY 1941	JANUARY 1940	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	2	0
Chicken pox	1574	2328	1924
Diphtheria	9	31	28
Dog bite	524	607	580
Dysentery bacillary	3	35	13
German measles	73	36	96
Gonorrhea	273	342	435
Lobar pneumonia	1052	673	725
Measles	1858	962	1833
Menococcal meningitis	8	7	8
Mumps	836	562	954
Paratyphoid B fever	5	5	1
Scarlet fever	592	565	963
Syphilis	296	421	413
Tuberculosis pulmonary	293	167	260
Tuberculosis other forms	25	21	29
Typhoid fever	4	8	6
Undulant fever	5	2	4
Whooping cough	1076	625	940

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Boston 1, Chelsea 2, Fall River, 3, Fitchburg 1, Medford, 1, Waltham, 1, total, 9

Dysentery, bacillary, was reported from Danvers, 2, Lynn, 1, total, 3

Infectious encephalitis was reported from Lowell, 1, total, 1

Malaria was reported from Chelsea, 1, total, 1

Meningococcus meningitis was reported from Boston 1, Chicopee 1, Framingham 1, Lenox, 1, Melrose 1, Middleboro 1, Newbury, 1, Taunton, 1, total, 8

Paratyphoid B fever was reported from Boston 2, Lowell 2, Malden, 1, total, 5

Pellagra was reported from Boston, 1, total, 1

Pfeiffer bacillus meningitis was reported from Attleboro 1, Chicopee, 1, total, 2

Septic sore throat was reported from Boston 8, Fall River, 3, Lexington, 1, Lowell, 1, Merrimack, 1, Oxford, 1, Springfield, 1, total, 16

Trachoma was reported from Boston, 1, Everett 1, New Bedford, 1, total, 3

Trichinosis was reported from Southbridge, 1, total, 1

Typhoid fever was reported from Somerville, 1, Springfield 1, Worcester, 2, total, 4

Undulant fever was reported from Athol, 1, Brockton 1, Gloucester, 1, Hudson, 1, Raynham, 1, total, 5

Chicken pox, dog bite, bacillary dysentery, German measles, mumps, scarlet fever and tuberculosis (other forms) were reported below the five year averages

Measles, tuberculosis (pulmonary) and whooping cough were reported above the five year averages

The incidences of meningococcus meningitis and undulant fever were not unusual

Typhoid fever showed low incidence

Diphtheria was reported at a record low figure for January

Lobar pneumonia was reported at the highest figure since the corresponding month in 1929

Paratyphoid B fever reached the record high figure of last January

CORRESPONDENCE

NOTICE TO BOSTON PHYSICIANS

To the Editor In order that physicians of Boston may more readily obtain outfits for the collection of sputum to be sent to the State Bacteriological Laboratory for pneumonia typing, such outfits are now available at any one of the forty-five culture stations throughout the city which are maintained by the City of Boston Health Department for the distribution and collection of its own bacteriological laboratory outfits, as well as for the distribution of all state-supplied biologic products. Any physician using such a pneumonia sputum outfit is responsible for its delivery to the State Bacteriological Laboratory at the State House, Room 527. This added service of the health departments concerned, emphasizes the value of pneumonia typing, particularly when it has been shown that chemotherapy is not the full answer in the treatment of pneumonia, and that physicians should be prepared to give serum therapy if good results with drugs are not obtained promptly.

G. LINDE GATEL, M.D., Health Commissioner,
City of Boston

REPORTS OF MEETINGS

BOSTON ORTHOPEDIC CLUB

A regular meeting of the Boston Orthopedic Club was held at the Boston Medical Library on December 16, 1940 with Dr. Augustus Thorndike, Jr., presiding. The Society was addressed by Dr. Stuart Mudd, professor of bacteriology at the University of Pennsylvania School of Medicine, on "A New Method for the Preparation of Blood for Use in the Treatment of Shock and Allied Conditions."

Dr. Mudd briefly reviewed the history of blood preservation. In discussing the technique of desiccating blood serum or plasma, he stated that solid carbon dioxide was too expensive, that anhydrous calcium sulfate was cheaper, owing to the reversibility of the process, and requires less attention but that the capacity for such a system is too small, and finally that the new vacuum pumps have a larger capacity and are more economical for large scale desiccation.

The speaker then went on to discuss the various uses of blood serum and plasma. One of the first for serum was in the prevention or treatment of specific infectious diseases of children and there are now several large centers scattered throughout the children's hospitals of the country. Placental immune globulin, introduced by McKhann, is now considered effective in decreasing the severity or incidence of complications in measles or in the prevention of this disease in institutions. Pooled convalescent serum has been shown on the average to decrease the incidence of scarlet fever in those exposed to the disease from about 14 to less than 2 per cent. It has also been used with variable results in the therapy of scarlet fever. The serum treatment of mumps, chicken pox and whooping cough is still in the experimental stage, and has not been accepted by the Council on Pharmacy and Chemistry of the American Medical Association but

the statistics appear promising. The treatment of poliomyelitis with convalescent serum in the preparalytic stage is still controversial. Pooled serum taken from young men from congested areas who have been made hyper-immune by injections of Sauer's vaccine has markedly reduced the morbidity and mortality of whooping cough in infants. The early use of convalescent serum in mumps appears advantageous, but it is probably ineffective after the virus has become intracellular, except to prevent involvement of new cells, especially those in the gonads. The results in chicken pox have not been so promising.

Serum and plasma, in concentrated form, may be employed to advantage in decreasing cerebrospinal-fluid pressure in operative cases or those of traumatic concussion. It is both logical and physiologic to use these substances, which contain both protein and electrolytes. The blood pressure rises as the spinal-fluid pressure drops. One hundred cubic centimeters of four-times concentrated serum was shown to decrease the pressure for two days. Dr. Mudd explained that although the increment of body plasma gained from such infusions is only 10 per cent, this may be enough to keep the intravascular osmotic pressure above a critical level. It was pointed out that the water balance of the patient at the time of treatment must be considered in determining how much serum should be given and in what concentration.

The third large group in which serum or plasma therapy is effective is in patients who become poor surgical risks because of hypoproteinemia, as in chronic gastrointestinal conditions. In such circumstances, healing is prone to be poor and wounds may open. Amino acid feeding has also been attempted. The intravenous use of serum or plasma in hypoproteinemia has proved effective.

The final conditions discussed by Dr. Mudd were secondary shock and burns, in which serum or plasma therapy is rapidly becoming the treatment of choice. In closing, the speaker observed that fresh serum or serum preserved in the fresh state may give a skin reaction, but that storage for some weeks in the liquid state seems to prevent this. It was suggested that this may be due to some labile substance involved in the clotting mechanism and preserved by immediate refrigeration. Plasma was considered the most ideal fluid.

The discussion was opened by Dr. Francis T. Hunter, of the Massachusetts General Hospital, who stated that there is no evidence that typing of serum or plasma is not necessary. He said that the suggestion had been made that all plasma might be made universally compatible by absorbing the agglutinins on the unused cells, but that this seemed to make the procedure more difficult rather than simpler than blood transfusion. Concerning the adoption of blood banks and the preservation of fluids, he stated that a centralized authority is necessary to maintain the proper standard, and that the advantages may not justify the expense.

Dr. Stephen J. Maddock, of the Boston City Hospital, remarked that the program is of more benefit to a municipal institution than to endowed hospitals, since in 1940 the outlay for blood transfusions at the Boston City Hospital was two and a half times that at the Massachusetts General Hospital. He added that liquid plasma was considered less expensive and easier to prepare than the dried form.

Dr. Benjamin Alexander, of the Beth Israel Hospital, — where a bank has been used for over a year, — expressed his satisfaction with the results to date. One hundred transfusions of whole plasma were administered without reaction in a period of eight months, during which 500 blood transfusions were given with only a few minor reactions. Dr. Alexander suggested that two types of

plasma be made: one in which all the possible blood constituents are preserved, and the other in which only the protein and electrolytes are saved by less delicate and easier methods. The latter material would be adequate for most cases of shock. He warned that the use of too much dried plasma in certain cases of shock might affect renal function by further increasing the prerenal deviation. The use of these materials has thus far proved ineffective in the nutritional edemas of hepatic cirrhosis.

Dr. Frank Barton, of the Massachusetts Memorial Hospitals, emphasized the importance of separating the liquid plasma before the blood begins to hemolyze. Cultures should be taken to ensure its freedom from contamination, and a specially trained group should do all the work. In his experience the average dose of plasma was 500 cc. Pooled plasma in amounts up to 1000 cc. was used in many cases, without reaction. In regard to cost, Dr. Barton stated that most outpatients are more than willing to donate 500 cc. of blood for \$7.50.

Dr. Joseph Porter, of the Maine General Hospital, stated that after having given 2700 transfusions without a death, there had been 4 in the last 500. Two of these undoubtedly could not be attributed to the plasma. In answer to a question about the feasibility of such a system in relatively small institutions, Dr. Porter stated that there are great advantages in avoiding haste in emergencies and the spasmodic swamping of the hospital with groups of donors. At the Maine General Hospital a complete physical examination of each prospective donor and a blood smear to rule out malaria are now required. Finally Dr. Porter raised the question whether the use of four-times concentrated serum might not lead to more reactions.

The discussion was closed by Dr. Mudd. He said that he did not believe that the adsorption of agglutinins is necessary, for reactions do not occur in practice. This may be owing to the fact that only pooled plasma is used, which may reduce the titer. Furthermore, the agglutinin receptors in the tissue help adsorb these substances. Dr. Mudd stated that although prothrombin and other more specialized elements are not necessary in the treatment of shock, such patients often have infection or some other superimposed condition that these "extras" may benefit. Blood is not a practical fluid for war use, and should be replaced by liquid or preferably dry plasma or serum, for ease of shipment and storage, especially in tropical countries. Dilute rather than concentrated plasma should be used in dehydrated patients in whom fluid is also needed.

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on January 7, with Dr. Aaron Thurman presiding. The speaker of the evening was Dr. Ephraim Shorr, of New York City, who discussed "Recent Advances in Female Endocrinology."

Instead of surveying the whole field Dr. Shorr discussed the vaginal smear as a method of approach to the diagnosis and treatment of certain conditions. It was admitted that it is not the only procedure, or even the best, and that it may not be applicable to every case; it is a clinical rather than a laboratory test, however, and therefore easily carried out. The development of this method from 1917, when vaginal changes were first correlated with the menstrual cycle in animals, to the present was reviewed. Dr. Shorr briefly described his technic of fixing and staining vaginal smears, and showed lantern slides of the changes in the normal cycle as a basis for comparison with abnormal conditions. During menstruation there

are red cells, white cells, mucous cells and some cornified epithelial cells. During the preovulatory stage, under the effect of estrin, there are largely cornified epithelial cells without any blood constituents. In the postovulatory period there are clumped epithelial cells, with less cornification, and some white blood cells. Then as the effect of progesterin is felt in the premenstrual period, there is moderate cornification and many clumped epithelial cells.

Dr Shorr then discussed certain conditions in which atrophy of the vaginal mucosa is found. At the menopause there is a decrease of cornification, the epithelial cells become smudgy and indeterminate, oval thecal cells appear, bacteria are found and there is an increase of leukocytes. Essentially the same picture is found in amenorrhea, in which there is marked atrophy owing to the absence of estrogens and in which oval cells and leukocytes predominate. The changes that occur in the smears during estrogen therapy were then reviewed: the cytoplasm of the cells changes from lavender to green, there is a decrease of leukocytes and a concomitant increase in the size and development of the epithelial cells, and the amount of cornification is proportional to the degree of replacement. A proliferative endometrium results, from which bleeding may occur four or five days after withdrawal, but with a persistent follicular smear instead of the usual postovulatory picture. Therefore the first half of the cycle can be produced by estrogen substitution therapy, but progesterin is necessary to complete the second half. The combination of these two hormones in castrates results in vaginal smears similar to the normal. Such smears may be of use, therefore, in determining the extent of replacement therapy with estrogens and in controlling treatment in cases of menopausal syndrome and amenorrhea. Using this method to evaluate the efficacy of various estrogenic hormones, it has been determined that it takes 2000 to 3000 rat units per day to cause full estrus in a human being and that all preparations given parenterally are equally effective. Orally about six times the parenteral dose is necessary to produce full estrus, it was further determined that estradiol is more potent than estrone, which in turn is more effective than estrin.

On the basis of vaginal smears, the loss of menopausal symptoms falls into four groups, varying from a slight change toward estrus to complete replacement. In other words, the symptoms are not always proportional to the type of vaginal smear, and a question arises whether other than organic causes account for the symptoms. It may be that there are at present immeasurable factors, for records reveal many cases of recurrence or relief of symptoms without any change of the vaginal smear. In an occasional patient the disappearance of symptoms may be due to recurrent spurts of ovarian activity, especially from the spring to the fall.

In discussing dosage, Dr Shorr pointed out that the parenteral route is, in the final analysis, the most economical. The wide spacing of doses was shown to be wasteful and inadequate for the production of estrus or the steady relief of menopausal symptoms. However, after determining what degree of estrogenic replacement a given patient requires for symptomatic relief, smaller or more widely spaced doses may be administered for those who require only a low degree of replacement, as measured by the vaginal smear, to remain asymptomatic.

Dr Shorr went on to discuss amenorrhea, of which there are primary and secondary forms. The first type,

the acyclic or atrophic form, is usually primary but may be secondary and has a continually atrophic vaginal smear. The second type is acyclic or intermediary and is always secondary, there may be some estrogen activity, but it is always diminished. The third type, which is also always secondary, is cyclic or subfunctional. The vaginal smear reveals a definite cycle of changes with some cornification and slight preovulatory bleeding, but the cycle is too small to produce normal menstruation. The method under discussion enables one to determine whether replacement therapy is indicated. It is necessary to have a previous control period so that one's results may be properly evaluated.

For the acyclic, atrophic form of amenorrhea, full replacement therapy with estrogens should be carried out. They should be administered every month for two years in doses large enough to give a cornified smear. Bleeding should occur on withdrawal. This therapy should be continued for several years. The effect of such therapy on the uterus is minimal, compared with that found in the secondary form of amenorrhea.

In following the results of the gonadotropic hormones on secondary amenorrhea, it has been shown that normal menstruation may occur even when there is no evidence of premenstrual activity. The androgens appear to have two different effects on the menopause. When they are administered to patients under estrogen therapy, there appears to be a peripheral neutralization of the latter as mirrored in the vaginal smear and symptoms. On the other hand, there is a definite alleviation of symptoms by androgen therapy in many cases, despite atrophic smears. It has been hypothesized that this is due to a depression of gonadotropic hormone, but the urinary level of this hormone is usually high. In the normal female there is a gradual onset of atrophic smears while the urinary estrogens are still high, therefore, the explanation is probably referable to a depression of the gonadotropic hormones rather than to a peripheral neutralization of the estrogens. The androgens must consequently be considered nonphysiologic, although they often have the desired effect. It was warned that these substances must be used with care and in the proper dosage. In conclusion, Dr Shorr referred to two cases of menorrhagia in which high doses of androgens failed to decrease follicular activity and in which operation revealed cystic ovaries.

The discussion was opened by Dr Samuel Gargill, who was very enthusiastic about the results obtained at the Beth Israel Hospital in ovarian dysfunction, especially in functional sterility. He pointed out that although all women at the menopause reveal the same vaginal smear, only about 40 per cent have symptoms. The most bothersome problem in amenorrhea has been the decision whether to supplement or to use substitution therapy. The discussion was closed by Dr Shorr, who suggested that this problem would persist until some indices for judging ovarian potentialities were found. Although primary amenorrhea is almost invariably acyclic and atrophic in form and associated with somatic defects, this condition can occur in secondary amenorrhea. This, therefore, seldom aids in determining which form of therapy should be employed. In closing Dr Shorr defined the menopausal syndrome—in answer to a question—as an unpleasant group of symptoms sometimes relieved by hormones and usually occurring at the menopause, but occasionally before or after.

MASSACHUSETTS MEDICAL SOCIETY

SPECIAL MEETING OF THE COUNCIL

A SPECIAL meeting of the Council of the Massachusetts Medical Society will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, April 9, 1941, at 10:30 a. m., by vote of the Council on February 5, 1941, as provided in Chapter IV, Section 1, of the by-laws.

Business: To consider various changes in the by-laws recommended to the Council at its meeting on February 5, 1941 by the Committee on Medical Education and Medical Diplomas and by the Committee to consider new officers and by-laws.

Incidental business.

ROBERT N. NYE, *Secretary pro tempore*.

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting luncheon will be served immediately after the meeting.

NOTICES

ANNOUNCEMENT

DR. ROBERT R. LINTON announces the opening of an office at 1101 Beacon Street, Brookline.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

A series of weekly clinics on disorders of the blood will be given by Dr. William Dameshek on Wednesday afternoons from 3:30 to 5:00 during April and May in the auditorium of the hospital, 30 Bennet Street. These informal presentations will deal with cases of anemia, leukemia, polycythemia, vitamin deficiencies and with certain aspects of the blood cells and bone marrow.

All physicians and medical students are welcome. Admission is free. Those who wish to attend must register in advance, either by telephone (HAN 5650) or by mail (Secretary of the Postgraduate Division, 30 Bennet Street, Boston).

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Thiede, formerly concertmaster of the Cleveland Symphony Orchestra, every Thursday at 8:30 p.m. Those interested in becoming members should com-

municate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

MASSACHUSETTS ASSOCIATION FOR OCCUPATIONAL THERAPY

"Occupational Therapy Pays Its Way" is the title of a dramatization to be presented by the Massachusetts Association for Occupational Therapy at the annual meeting of the New England Hospital Assembly, March 14, at

the Hotel Statler. In a series of four skits it will show how occupational therapy has become a valuable aid in the care of the ill through scientifically applied activity directed toward physical, social and economic rehabilitation.

Represented in the cast will be Dr. Roy D. Halloran, superintendent of the Metropolitan State Hospital and president of the Massachusetts Occupational Therapy Association. Others include therapists from the Robert B. Brigham, Massachusetts General, Children's, Faulkner and McLean hospitals and the Boston School of Occupational Therapy.

MASSACHUSETTS SOCIETY FOR RESEARCH IN PSYCHIATRY

The next meeting of the Massachusetts Society for Research in Psychiatry will be held at the Grafton State Hospital on Thursday, March 13, at 8 p. m.

PROGRAM

Osteitis Deformans Associated with Mental Disease.
Drs. E. V. Semrad and R. Wadsworth and Mr. S. Horwath.

Creatinine-Creatine Excretion in Schizophrenia. Dr. W. Corwin and Mr. S. Horwath.

Report of Committee on Convulsive Therapy, with discussion of plans for the May meeting.

SOUTH END MEDICAL CLUB

There will be a meeting of the South End Medical Club at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, March 18, at 12 m. Dr. Francis M. Rackemann will speak on "Asthma: Its treatment."

Physicians are cordially invited to attend.

MASSACHUSETTS TUBERCULOSIS LEAGUE

The annual meeting of the Massachusetts Tuberculosis League will be held on Thursday, March 20, at the University Club, Trinity Place and Stuart Street, Boston.

PROGRAM

11:00 a.m. Business meeting.

12:30 p.m. Luncheon.

1:45 p.m. Presidential Address. Dr. Frederick T. Lord.

Keeping Up to Date on Tuberculosis Patients. Dr. Alton S. Pope.

How Are State Rules and Regulations Regarding Tuberculosis Being Carried Out? Miss Margaret S. Boyle, R.N.

3:30 p.m. Board of Directors' meeting.

The charge for luncheon will be \$1.00 per person. Reservations should be sent to: Massachusetts Tuberculosis League, 1148 Little Building, Boston. Tel. HAN 5480.

FREE PUBLIC LECTURES

The Quincy City Hospital, in conjunction with the Social Service Committee, is offering a course of free health lectures to be given in the Administration Building of the Hospital at 3 p.m. on Sundays. The schedule is as follows:

March 9. First Aid: What to do in any emergency. Dr. Frederic N. Manley.

March 16. Diet and Care of Infants. Dr. Edmund Fitzgerald.

- March 23. Diet and Reducing: How to retain that ideal weight. Miss Marjorie L. Foster.
- March 30. Signs, Symptoms and Treatment of Cancer. Dr. Walter L. Sargent.
- April 6. "Magic Bullet" and Venereal Diseases. Dr. Edwin E. Smith.
- April 13. Fractures, Broken Bones, X-rays and Splints. Dr. F. Ramon Burke.
- April 20. Signs, Symptoms and Treatment of Appendicitis. Dr. J. Edward Knowlton.

NEW ENGLAND OTO-LARYNGOLOGICAL SOCIETY

The regular spring meeting of the New England Oto-Laryngological Society will be held on Wednesday, March 19, at the Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston, at 4 p.m. The evening program will be devoted to a symposium on "The Management of Some of the Complications Arising from Acute and Chronic Otitis Media." Discussion will follow by Drs. Harold Tobey, Charles T. Porter, Maxwell Finland, Champ Lyons, W. Jason Mixer and Charles S. Kubik.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MARCH 9

SUNDAY, MARCH 9

- 11 p.m. The Pathway of Medical Discovery Dr. Reginald Fitz Free public lecture. Harvard Medical School, Building D

MONDAY, MARCH 10

- 12 15-1 15 p.m. Clinicopathologic conference Peter Bent Brigham Hospital amphitheater.

TUESDAY, MARCH 11

- 9-10 a.m. Psychiatric Examination of Recruits Dr. A. W. Stearns Joseph H. Pratt Diagnostic Hospital
- 12 15-1 15 p.m. Clinicoradiogenologic conference Peter Bent Brigham Hospital amphitheater.
- 8 p.m. Ten Years' Experience with Avertin Drs. G. A. Leland and R. F. Sheldon New England Society of Anesthesiology Massachusetts General Hospital, Waite Auditorium
- 8 15 p.m. Harvard Medical Society. Peter Bent Brigham Hospital amphitheater.

WEDNESDAY, MARCH 12

- New England Hospital Assembly. Hotel Statler
- 9-10 a.m. Hospital case presentation Dr. S. J. Thinnhauser Joseph H. Pratt Diagnostic Hospital.
- 12 m. Clinicopathologic conference Children's Hospital

THURSDAY, MARCH 13

- New England Hospital Assembly. Hotel Statler
- 8 30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital
- 9-10 a.m. The Enzymatic Breakdown of Carbohydrates Dr. G. Schmidt, Joseph H. Pratt Diagnostic Hospital
- 8 15 p.m. Mechanical Derangements of the Knee Dr. Edwin F. Carey United States Naval Hospital, Chelsea

FRIDAY, MARCH 14

- New England Hospital Assembly. Hotel Statler
- Massachusetts Association for Occupational Therapy. Hotel Statler
- 9-10 a.m. The Neurologic Complications of Some of the Common Contagious Diseases Dr. R. C. Eley Joseph H. Pratt Diagnostic Hospital

SATURDAY, MARCH 15

- 9-10 a.m. Hospital case presentation Dr. S. J. Thinnhauser, Joseph H. Pratt Diagnostic Hospital

*Open to the medical profession
*Open to the public

BOOK REVIEWS

Medical Nursing. By Edgar Hull, M.D.; Christine Wright, R.N., B.S., and Ann B. Eyl, B.S. 8", cloth, with 168 illustrations, including 11 color plates. Philadelphia: F. A. Davis Company, 1940. \$3.50.

This textbook for nurses, written by an internist, a nurse and a dietitian, is the answer to the busy student nurse's prayer. It is a concise, authoritative book, written from the nurse's standpoint.

Not only are the medical subjects adequately treated, but each chapter also contains a discussion of the special nursing problems involved. A presentation of pertinent dietetic factors adds to the value of the text. The subject matter in general is handled thoroughly, is distinctly up to date and deals not only with diseases of the system, but also with such subjects as the deficiency diseases, metabolism and allergy. There are adequate discussions of chemotherapy, the use of Dilantin in epilepsy, and some of the more recent uses of dihydrotachysterol in hypoparathyroidism. Proper emphasis is placed on the necessity for avoiding starvation diets in cases of peptic ulcer.

A book by three authors inevitably contains occasional overlapping or omission of some subject matter. Thus one finds a detailed description of the diet for patients

suffering from chlorosis, but the authors fail to describe the disease itself. Such oversights are few, however, and detract little from the excellence of the book. The print is clear, and the division of each page into two columns ensures easy reading.

This book is recommended as a worthwhile addition to the nurse's library.

A Manual of Neurohistologic Technique. By Oscar A. Turner, M.D. 4°, cloth, 73 pp. St. Louis: C. V. Mosby Company, 1940. \$2.00.

This valuable contribution to neurohistologic technic is to be commended for the clarity and conciseness of its presentation. It is intended for technicians working in a general pathological laboratory. The methods considered may be carried out on formalin-fixed tissues. A bibliography has been included for those who wish to delve further into the subject. The last few decades have added much to the nature and function of the nervous system, and this book will serve to give insight into some of the steps taken in this direction.

Public Health Administration in the United States. By Wilson G. Smillie, A.B., M.D., Dr.P.H. Second edition. 8°, cloth, 553 pp., with 22 figures, and 9 plates. New York: Macmillan Company, 1940. \$3.75.

Public-health administration differs considerably in the various parts of our country. Even in a circumscribed location, rural, municipal, state and federal health administrations and the voluntary health organizations may well show diversified practices. Public-health administration must necessarily be based on preventive medicine. The principles of preventive medicine are constantly changing, and with them public-health administration.

In his earlier volume Dr. Smillie selected public-health administrative methods that had been employed by competent men and had been proved to have merit. In the present volume he has included the changes that have occurred during the preceding five years.

Owing to the Social Security Act of 1935, public-health activities have made more advances during the last five years than they did during the previous quarter of a century. Improvement in administrative procedures in the control of scarlet fever, typhoid fever, measles, whooping cough, influenza, syphilis, gonorrhea and pneumonia has necessitated a revision of the chapters on these diseases in the light of present knowledge. Knowledge concerning nutrition has increased appreciably, and community efforts to improve nutrition have made important changes in health programs. The public-health administration for epidemic encephalitis, tularemia and trichinosis has been added to this volume.

An appendix is furnished that gives qualifications for various health personnel and a two-foot reference shelf for local health departments. Comprising about one hundred pages more than the previous edition, this volume should be indispensable to the local health administrator.

Inasmuch as concise information is furnished regarding therapy and epidemiology of a large number of diseases that the physician will meet in his practice, this volume should be of interest to the general practitioner.

Tuberculosis and Genius. By Lewis J. Moorman, M.D. 8°, cloth, 272 pp., with 10 portraits. Chicago: University of Chicago Press, 1940. \$2.50.

Since the victims of tuberculosis have been herded together in sanatoriums, forced to submit to the tyrannical rules of community life and restrained to a purely vegeta-

tive existence, they have reacted in various ways to the abnormal conditions thus imposed upon them. Struck by some of these reactions, numerous clinicians have felt the urge to become amateur psychiatrists, and have tried their newly discovered talent on the rich material placed at their disposal by a kindly providence. Such tentatives are noble inasmuch as they mean an effort to understand and to help the sick. They become less than useless when they serve as a foundation for fantastic theories.

Tuberculous patients have been branded as dissolute erotics and beautified as angels of chastity; they have been described as ferocious egotists and also presented as generous Don Quixotes; they have been shown to cower abjectly in the presence of illness and then to bear its trials heroically; they have been seen to despair at the thought of death, and on the contrary, to exhibit the traditional *spes phthisica*; they have been alternately relegated among the morons and exalted to the rank of geniuses. The poor wretches! So bad and yet so good! So low and still so high! Are they really different from the rest of humanity? Why attribute any of their traits to the tubercle bacillus? The nervous cells may be influenced, to some extent, by the physiologic alterations resulting from a disease—any disease—and the psyche may feel some repercussions. The reactions will manifest themselves by an accentuation of the natural traits of the individual temperament, so slight as to be imperceptible in most cases. Far more important than this biological factor is the commotion resulting from the moral upheaval that is the necessary accompaniment of illness: fear of death, physical pain, humiliation, financial worries, idleness, lonesomeness, and so forth. These being in direct proportion to the seriousness of the disease and to the length of treatment it requires, is it any wonder that tuberculosis ranks first among mental disturbers?

So much for the patients who are known to be tuberculous and who are themselves aware of their condition. When it comes to excursions into history such as that of Dr. Moorman, to diagnoses based on assumptions and to theories soaring to such heights as the seventh heaven of genius, one has the right to feel dizzy!

First, even the diagnoses are to be questioned. Take the case of Voltaire. Could not he have had bronchiectasis instead of tuberculosis? Could not he have been a dyspeptic? He had the facies of one. If he did have tuberculosis, the bacilli that took eighty-four years to kill their man were not sufficiently biting to sharpen the incisiveness of his cynical wit. Besides, to be certain that the spark of genius was kindled or even made brighter by the tubercle bacillus in any of these powerful minds one would have to eliminate all other possibilities. Knowing the artistic temperament, one may be permitted to suggest the existence of a sprinkling of spirochetes.

The author's theory itself may also be challenged, for it is entirely based on assumptions and beliefs. In his twenty-five-page introduction, he records the opinions of numerous writers concerning the influence of tuberculosis on the minds of those suffering from the disease. They run as follows: "Some authorities have held that. . . ." "Some people ascribe their genius to. . . ." "It is entirely conceivable that the tuberculous byproducts are capable of. . . ." "Erick Stern is inclined to attribute the manifestations of genius to the toxic action. . . ." All this is too weak for a foundation.

Genius transcends contingencies. Molière, Keats and Shelley would have been Molière, Keats and Shelley, regardless of their tuberculosis, just as Balzac, DeQuincey and Poe would have written beautifully without coffee, opium and alcohol. Let us continue to show to our pa-

vents those mighty figures and to point to their accomplishments in the face of handicaps. To tell them that the creative power of genius is enhanced by the toxins of such or such a germ would seem to be unjustifiable.

The Neuroses in War. By several authors under the editorship of Emanuel Miller, MA (Cantab), MRCP, DPM (Camb), with a concluding chapter by H. Crichton Miller, MD, FRCP. 8°, cloth, 250 pp. New York: Macmillan Company, 1940. \$2.50.

A group of authors under the guidance of Dr. Emanuel Miller have written about their experiences in World War I in regard to the care of soldiers suffering from psychoneuroses. The whole subject, including the early literature, is carefully reviewed, and authorities in special fields discuss the particular problems associated with the psychoneuroses. The book, therefore, should form an excellent basis for the care of the psychoneuroses as they develop in World War II. A little has been added, in the form of an appendix, about the treatment facilities in 1940 for civilians, and there are a few pages on psychiatric pharmacology, a subject that has become important in the last year. Some reports have appeared in regard to the treatment of men evacuated from Dunkirk with drugs, particularly those of the narcotic type used as a basis for psychotherapy. The value of this method is not by any means widely accepted, but the fact that it is being used justifies the inclusion of a brief notice in this book.

The volume, in general, is of value as a summary of our knowledge of the psychoneuroses under war conditions and as an indication of how patients so afflicted ought to be treated in the present emergency.

Clinical Diabetes Mellitus and Hyperinsulinism. By Russell M. Wilder, MD, PhD, FACP. 8°, cloth, 459 pp., with 19 illustrations. Philadelphia and London: W. B. Saunders Company, 1940. \$6.00.

In this excellent monograph are summarized the clinical experience of the author during twenty-five years largely devoted to diabetes mellitus. Emphasizing the complexity of the subject, he has purposely omitted extensive consideration of the theory of carbohydrate metabolism, the physiology of experimental diabetes and the pathology of diabetes. He adheres to the unitarian conception of diabetes—an abnormality of metabolism due to insufficiency of the insulin activity of the pancreas. The homeostasis of the blood sugar level is permanently disturbed, a fact that distinguishes diabetes from all other conditions including diseases of the liver, central nervous system and endocrine glands, in which hyperglycemia, if it occurs, is but temporary. The primary cause of diabetes is therefore an inadequate insular reserve. The influence of the pituitary gland, adrenal glands and liver is important in regulating the level of the blood sugar, but not in the primary causation of diabetes. The author stresses the hereditary inferiority of the insular reserve.

Almost all patients at the Mayo Clinic who require insulin are given protamine zinc insulin. Methods and dosages are discussed in detail. Nearly fifty pages are devoted to dietary treatment. The many complications, including acidosis, surgery, pregnancy and diseases of the nervous system, liver, arteries, skin, genitourinary tract, thyroid and pituitary glands, receive careful clinical presentation. The important subject of hyperinsulinism, with special reference to tumors of the islets of Langerhans, is given forty pages and will be found worthy of careful study by any physician faced with the difficult problems of diagnosis and treatment when this condition is suspected.

Organization, Strategy and Tactics of the Army Medical Services in War. By Lieutenant Colonel T. B. Nicholls, MB, ChB. With chapters by Air Commodore A. S. Glynn, MB, ChB, KHS, RAF, Colonel A. R. Laurie, MB, ChB, DMRE (TA), and Colonel F. G. Lescher, Medical Corps, MA, MD, MRCP (TA). 8°, cloth, 488 pp. London: Baillière, Tindall and Cox, 1940. Obtainable in the United States from Williams and Wilkins Company. \$5.00.

The second and enlarged edition of this book by Lieutenant Colonel Nicholls is a valuable contribution to military medical literature. The author's wide experience during World War I, in the Royal Army Medical Corps, of the British Expeditionary Force, when he commanded almost every kind of unit in the field, has given him a thorough grasp of the needs and difficulties of the medical department in war. The text of this edition has been revised so that the pages can be more easily read, and emphasis has not been placed, as in the previous edition, on every trivial statement.

Part I discusses general principles. The magnitude of the organization, the necessary personnel and enormous amount of equipment of the medical services of a nation in modern war are adequately described. Not only must the medical services be equipped to care for large numbers of casualties, but they must also be able to evacuate promptly all those able to be moved. Medical officers should have in mind, at all times, the primary objective of returning all casualties rapidly to duty, in other words, to conserve the man power of the nation at war.

The following fundamental principles are stressed: the first duty of the medical services is the preservation of the health of the troops, a reserve of supplies and personnel must always be kept, time spent in reconnaissance, by medical officers in command, is rarely wasted, tactical requirements must be pre-eminent, so that the demands of the medical services take second place, the collection, professional care and treatment of sick and wounded, as well as their evacuation, are duties of the medical services.

The chapter, "General principles," is of value in pointing out to medical officers the fundamentals on which action of the army, as a whole, is based. If the medical officer in command of a unit understands these seven principles, his own activities will be intelligent, and his ability to meet and solve his problems will be greater. The chapter, "The appreciation of the situation, deserves careful study. The chapter, "Calculation of casualties," with a double page table of casualties in the battles of World War I, gives a striking picture of the sudden heavy burdens thrown on the medical services.

Part II takes up in detail the organization and equipment of each medical unit, from front to rear: regimental aid post, advanced dressing station, main dressing station, casualty clearing station, and so forth. It includes a new section, "Transportation of casualties by air," which is in structure, although more applicable to desert and frontier warfare, as in India, Egypt or Iraq.

Part III, strategy and tactics, with application to the medical services, is important. With a good knowledge of them, an officer will be able not only to understand better his orders and instructions, but also to adapt his medical organization to the varying conditions of the battle, as well as possibly to anticipate the outcome.

Part IV, "Medical Arrangements for Military Casualties at Home," by F. Graham Lescher, of the Emergency Medical Services, covers a new and, at present, very important subject. Truly a war between nations, as carried on now, is a war on men under arms as well as on women and children—barbarous and cruel.

Part V, "Problems and Exercises," is primarily for officers of the Royal Army Medical Corps, and therefore is less useful to medical officers of the United States Army.

The list of abbreviations used in the text, with their meanings, a full index, which needs some corrections, and blank pages for memoranda and notes, at the end, add value to the volume. The book can be strongly recommended for study and reference by military medical officers.

The Injured Back and Its Treatment. Edited by John D. Ellis, M.D. Contributing authors: H. Earle Conwell, M.D., Loyal Davis, M.D., Nathan S. Davis, III, M.D., John D. Ellis, M.D., Ralph K. Ghormley, M.D., Hale A. Haven, M.D., Professor Sir Arthur Keith, F.R.C.S., F.R.S., and Robert B. Osgood, M.D. 4°, cloth, 377 pp., with 156 illustrations and 3 tables. Springfield, Illinois: Charles C Thomas, 1940. \$5.50.

In this book a group of well-known industrial and orthopedic surgeons have collaborated to give a complete account of the present knowledge of spinal injuries. The book is well edited, and the illustrations are good. Beginning with a discussion on the acquisition of the upright posture in man, it reviews in turn the physiology of referred pain as well as local pain in relation to various injuries of the back, and then discusses the various etiologic factors that produce spinal disabilities. The chapter on examination of the back is one of the best parts of the book; it covers satisfactorily all the things that the examiner should consider and then gives a helpful summary for the interpretation of the findings.

Treatments of all types are discussed. Since this treatise is written primarily for those who already have some familiarity with spinal injuries, the discussion of treatment and of the various indications is probably adequate. However, the outline of treatment is not sufficient as a guide for the general practitioner, for whom a fuller description of therapy and a discussion of what not to do would be helpful. One would like to see also a fuller account of therapy for the more chronic disabilities of the spine, particularly those in patients who fail to get well under the simple, indicated types of treatment. There is no mention of treatment in Marie-Strümpell disease and osteoarthritis, or in slowly progressive metastatic cancer involving the spine. All these not infrequently must be considered in the diagnosis and treatment of spinal injuries. The book is well arranged and well written. A complete bibliography follows each chapter. It should be a valuable reference book for orthopedic and industrial surgeons, and is recommended without hesitation as the best treatise on spinal injuries yet published in the English language.

The Life of Sir William Osler. By Harvey Cushing, M.D. Complete in One Volume. 8°, cloth, 1417 pp., with 10 illustrations. New York: Oxford University Press, 1940. \$5.00.

Harvey Cushing's *Life of Sir William Osler* is one of the great medical biographies. Few books written about doctors give such a fine picture of a medical colleague. It was first published in two volumes in 1925, with numerous illustrations, being priced at \$12.50. Many medical students, for whom the book was intended, were unable to purchase it because of the expense, and therefore the same work, without deletion so far as the text is concerned, has been issued in a single volume for \$5.00.

Unfortunately, the present edition is not quite what one would desire. Many of the illustrations of the first edition have been omitted, and for the original frontispiece, one of the most charming illustrations of a doctor ever reproduced, a photograph of the Vernon Plaque has been substituted. The profile is hard and cold, and reflects nothing of Osler's warmth and charm, characteristics so strongly a part of his personality.

There is evidence, moreover, of considerable haste in compiling this volume. Some of the corrections printed subsequent to the issue of the first edition have been incorporated in the new work; others have been omitted, and some have been "corrected" incorrectly. In the leaflet issued in connection with this edition, there are a number of errors, some of which can be attributed only to gross carelessness on the part of the publisher. In one picture, for example, a young man standing beside Sir William Osler is identified incorrectly as his son.

Finally, the book is too heavy and large for convenient handling. Medical students are more likely to avoid such a book than to read it thoroughly. It is the kind of work that should form part of a "Bedside Library," similar to that advocated by Osler himself. Surely, this awkward, heavy volume is not the kind of book that anyone would read in bed.

There is also to be issued, according to the leaflet, a two-volume edition, priced at \$10.00. No indication is given whether or not this is a reprint of the original, with all illustrations. If it is a true reprint, with the corrections properly made, any medical student wishing to acquire this biography of the greatest physician developed in the Western Hemisphere would do well to purchase the more inclusive volume.

The Compleat Pediatrician: Practical, diagnostic, therapeutic and preventive pediatrics. By Wilburt C. Davison, D.Sc., M.D. Third edition. 8°, cloth, 256 pp. Durham, North Carolina: Duke University Press, 1940. \$3.75.

In publishing *The Compleat Pediatrician*, Dr. Davison has imposed a great debt of gratitude not only on specialists, but also on all doctors charged with the care of children, sick or well. For the word "compleat" in the title is no misnomer. The whole body of pediatrics is compressed in this book, which is not too big to carry in pocket or bag.

The arrangement — if there are any who are unfamiliar with the book — is encyclopedic; it is a pediatric Baedeker. To investigate a problem of practice one may start from one of several angles, either with the name of the disease or with the presenting symptoms. In any case, through the cross references he will be carried through differential diagnosis to such laboratory procedures as are needed to confirm or deny his suspicions. If treatment is in doubt or if there are questions relating to growth or development, to hygiene or to disease prophylaxis answers may be found. The book is an inexhaustible mine of facts that are forever eluding one's memory. And, as Dr. Davison truly says, "a mere reminder often makes a physician the master of a situation."

In structure this third edition closely follows the second, but it has involved the changing of some 10,000 lines, and it contains the essential information from 3700 additional articles. It is a book that will grow on a man with use; indeed the reviewer is free to say that if he were to be restricted to a single book in this field, *The Compleat Pediatrician* would be his choice.

NUMBER 11

FACTORS IN THE REDUCTION OF MORTALITY FROM PULMONARY ABSCESS*

RICHARD H. OVERHOLT, M.D.† AND WILLIAM R. RUMEL, M.D.
BOSTON

SINCE the time of Hippocrates¹ reports concerning the management of lung abscess have appeared periodically in the medical literature. In the last two decades the frequency of these reports has increased greatly, but their substance, so far as results are concerned, remains much the same—to the distress of all who read of failure to treat ade-

or in various combinations supportive therapy, drug therapy, postural drainage, bronchoscopic aspiration and pneumothorax treatment. The dismal results obtained by these measures are presented in Table 1. The second is the uniform, almost stereotyped conception of leading authorities about the proper management of the patient with abscess of the lung. This conception is, essentially, that such a patient should be treated by a strictly conservative and supportive regime for at least six to sixteen weeks, or until he proves that he needs additional aid by his rapidly declining course, which threatens to terminate fatally under

quately this serious disease. There has been a failure in spite of the tremendous amount of research that has been done on the subject, in spite of vast improvements in diagnostic facilities and in spite of great progress in the development of therapeutic measures, including the recently introduced chemotherapeutic agents.

In making a critical study of the extensive literature that has accumulated, one cannot help being struck by several salient facts. The first is the failure of conservative treatment alone in all well-controlled series. This is meant to include the application of the following measures, either alone

the existing form of treatment. Only after this trial period, or after the patient has run his swiftly failing course, should surgery be carried out. This plan of treatment has not been significantly altered in the last forty years. In practice this combined management has also failed, as Table 2 shows. Such high mortality rates and low cure rates condemn this type of management, which has been given adequate trial. The third striking fact encountered is that unquestionably surgery in its broadest meaning must also be classed with

*Presented at the annual meeting of the New England Surgical Society, Poland Spring, Maine, September 28, 1940.

†Consulting surgeon, New England Deaconess Hospital.

the therapeutic measures that have failed. In a group of 2114 collected cases of surgically treated lung abscess, reported by Allen and Blackman,¹⁰ the mortality rate was 34.2 per cent. We believe that future statistics will prove that surgery will continue to fail so long as this term is used to include a multitude of operative procedures, the value of which has been conclusively disproved by uniformly bad results.

Inasmuch as practically all the reports in the literature were based on hospitalized cases, it caused us to wonder whether some patients recover from abscess of the lung without being admitted to an institution, and whether the disease is actually so serious as the reports led us to believe. To determine whether or not this was true, we made a survey of 100 patients with lung abscess, proved by clinical history and chest roentgenograms. This study was made possible by the co-operation of various diagnostic clinics, sanatoriums and private offices, where patients in all stages of the disease are seen, including some patients who recovered without hospitalization. However, much to our dismay, we found that even in this highly representative group of cases the results were not far different from those in the other reported cases. Thirty-one patients died of the disease. Persistent symptoms were present in 20 of the group. Forty-nine were asymptomatic.*

What, then, is the answer to this problem? To date the most hopeful solution is found in the reports coming from Dr. Harold Neuhof and his associates, in which lung abscess is treated as a surgical problem from the onset, and immediate and early drainage is employed. The most recent publication from his clinic¹⁴ concerns the results of this type of treatment in 104 consecutive cases. There were 4 deaths in the series, and the vast majority of the survivors were cured. It is our firm belief that anyone can obtain similar results if, and only if, he abides by the sound pathological and surgical principles on which this excellent work is founded.

The purpose of this paper is to present our conception of the proper management of lung abscess, based largely on the results obtained in treating 95 cases in the last eight years. In the group of patients treated by various generally accepted therapeutic measures, excluding external drainage and excision, the mortality rate was 53 per cent, and the cure rate 26 per cent. In the group of patients treated by lung resection the mortality rate was 23 per cent, the cure rate 62 per cent. In the group treated by external drainage at an advanced stage of the disease the mortality

rate was 32 per cent, and the cure rate 26 per cent. *In the group of patients treated by external drainage at an early stage of the disease the mortality rate was 6 per cent, and the cure rate was 94 per cent.* The cases in the latter group are comparable to the ones reported by Neuhof and Touroff.¹⁴

DEFINITION

Lung abscess may be defined as any suppurative infection with cavitation, arising primarily as a result of implantation of a group of pyogenic organisms in the periphery of the tracheobronchial tree. This therefore includes all such conditions described in the literature as "pulmonary abscess" or "pulmonary gangrene," many cases described as *suppurative disease of the lung* or "pulmonary suppuration" and cases of "acute putrid abscess of the lung" or "aputrid abscess." We have excluded only the following types: those primarily a part of a general pyemia; those which are tuberculous; those secondary to unquestioned primary bronchiectasis; and those secondary to pulmonary tumors.

PRACTICAL PATHOLOGICAL CONSIDERATIONS

Several fundamental pathological considerations are of definite practical value and therefore deserve discussion.

Bacteriology

Our bacteriologic studies have been of help in a single but important way. They have emphasized the generally accepted fact that the majority of lung abscesses are caused either by strictly anaerobic organisms or by a combination of aerobes and anaerobes. It is therefore imperative to establish early and adequate oxygenation of the abscess cavity, if the concentric invasion of the histolytic bacteria is to be stopped. The consistent and dramatic conversion of a ragged, putrid-smelling abscess cavity into a clean, odorless, granulating wound in a short period, after the use of zinc peroxide paste, has demonstrated to us the value of adequate oxygenation. The rapid reversal of this reaction during the early postoperative period, when the chemical is omitted, indicates that it is very beneficial to supply even a greater amount of oxygen than an adequate external drainage tract affords.

Location

The location of an abscess, with relation to the surface of a pulmonary lobe in which it is situated and with relation to the limiting surfaces of the pleural cavity, is of great importance. The position of 91 abscesses in our group was definitely

*Cure was not used because final roentgenograms to rule out the presence of persistent infiltration were not available in many cases.

determined (Table 3 and Fig. 1). All the abscesses were located peripherally with regard to the lobe in which they were situated. Furthermore, a portion of the wall of the cavities was in juxtaposition

duration. Since all abscesses are almost invariably located peripherally and since pleural symphysis develops at an early stage of the disease, it is possible to employ external drainage early and as a

TABLE 3. Location of 91 Abscesses.

LOCATION	RIGHT LUNGS			LEFT LUNGS			ALL LUNGS

to the surface of the pulmonary segment. Thus in the vast majority of cases the abscesses were readily accessible for surgical drainage.

Condition of Overlying Pleura

The presence or absence of pleural symphysis, overlying the abscess, has a vital bearing on surgi-

single-stage procedure, with the provision that localization is accurate.

Contents of Cavity

To us the most outstanding pathological consideration concerns the contents of the cavity. In the great majority of cases of abscess of the lung the cavity contains not only fluid pus, but also a semisolid slough of necrotic lung tissue and debris. The presence of solid debris within the cavity has been mentioned by previous writers, but the role it plays in the prevention of solid healing of the cavity has not been emphasized. It is one of the principal causes of failure of all therapeutic methods based on internal drainage. This mass of amorphous debris interferes with oxygenation of the cavity and obstructs drainage of the communicating bronchus. In a small percentage of cases the bronchial opening is large enough, or the slough becomes sufficiently liquefied, to permit its evacuation via the bronchus. Should this mass find an

cal management. We were able to determine definitely the condition of the pleura overlying 84 abscesses. With only three exceptions, pleural symphysis between lung and chest wall was present (Table 4). In two of the three exceptions the abscesses pointed on the interlobar fissure, where adhesions were present. It is noteworthy that adhesions were present just as consistently in the group of lesions under six weeks in duration as they were in the group of greater

*Abscess secondary to aspiration of foreign body.

exit, complete recovery with conservative methods of treatment may follow. However, in the vast majority of cases the bacteria-laden mass becomes more or less inspissated and encapsulated, acting as a foreign body that prevents union of cavity

walls, and solid healing fails to take place. Not only does it prevent solid healing, but it acts as a bomb, teeming with virulent and invasive bacteria, which constantly menaces the life of the patient until it is removed. At any time the delicate balance between the patient's resistance and the destructive force of the bacteria may be upset, and the patient may develop one of the fulminating exacerbations so characteristic of lung abscess. A patient, even though asymptomatic, should never be considered cured and out of danger until careful roentgenographic examination proves that there is no persistent intrapulmonary infiltration, however small, indicating the presence of such a focus.

Pathological Classification

We have found it helpful to separate the lesions, according to the stage of development, into two groups: simple lung abscess and complicated lung abscess. The characteristics of the two stages are summarized as follows (Figs. 2, 3, 4 and 5):

SIMPLE LUNG ABSCESS	COMPLICATED LUNG ABSCESS
Primary cavity unilocular or multilocular.	Same.
Contents of cavity fluid pus, usually with necrotic slough or semisolid debris.	Same.
Abscess located peripherally in lobe.	Same.
Early pleural symphysis present.	Symphysis usually less extensive if abscess is chronic.
Zone of pneumonitis, varying in width, surrounds primary cavity.	Same, except zone is more extensive.
No daughter abscesses in zone of pneumonitis.	Single or multiple daughter abscesses present in zone of pneumonitis not located superficially and not communicating with the primary cavity.
Secondary bronchiectasis absent.	Secondary bronchiectasis present.
Fibrosis minimal.	Fibrosis minimal to very marked.
Duration: approximately four fifths of cases are under six weeks.	Duration: approximately four fifths of cases are over six weeks.

By correlating the preoperative roentgenographic findings and the observations made during and immediately after operation, it is possible in almost every case to determine whether an abscess falls into the simple or the complicated group. We realize that such a classification is not ideal, inasmuch as it is not possible in many cases to distinguish between a simple multilocular abscess and a complicated one, with its associated daughter abscesses, on roentgenographic appearances alone.

In spite of this objection we believe that it is far superior to a purely chronological classification, which gives no consideration to the disease present. To evaluate the results accurately it must first be determined with what one is dealing pathologically. In cases of simple lung abscess all locu-

FIGURE 2. Diagram of a Simple Abscess.

The single abscess cavity is usually multilocular. Semisolid debris within the cavity is a common finding. Note the small caliber of the draining bronchus. Frequently the communicating bronchus becomes partially or completely occluded either with caseous debris from the center of the cavity or from edema of its mucosa

lations—if present at all—communicate freely with the primary cavity; there is no secondary bronchiectasis, and the amount of fibrosis is minimal. Therefore, one simple incision and drainage of the primary cavity of a complicated abscess can by no means be expected to effect a cure. The persistent isolated daughter abscesses and bronchiectatic dilatations act as reservoirs of smoldering infection, which at any time may flare up into a fulminating pneumonitis or gangrene. When such a course of events follows external drainage of a complicated lung abscess, it is much more probable that it is due to persistence than to recurrence of the disease.

Surgical Danger Zone

Another surgical pathological consideration that deserves special emphasis is that incision, cauterization or any other manipulation of the zone of pneumonitis that surrounds all abscess cavities must be religiously avoided. This zone may very properly be called the "surgical danger zone," because any encroachment on it is attended in certain cases by alarming and even fatal complications. The same warning applies to the traversing of normal lung tissue in an approach to the cavity. Such disturbance breaks down Nature's defense mechanism, which is pitted against virulent and invasive bacteria, thus favoring the development

of a rapidly spreading and frequently fatal pneumonitis. It also invites the next most important group of complications, which are caused by em-

lodgment of septic emboli; other temporary or permanent signs of intracranial involvement such as psychosis or hemiplegia; and generalized pyemia.

FIGURE 3. Posteroanterior (A) and Lateral (B) Roentgenograms.

This was a lung abscess of unknown etiology in a boy of twelve; it had been present for three weeks, with the condition becoming steadily graver. The abscess in the upper lobe developed in the beginning, with rapid spread of infection to the lower lobe, and the development of a second cavity there. Note the fluid level in one of the cavities. Separate thoracotomy for each abscess and single-stage drainage resulted in prompt recovery with complete healing.

boli that arise as a direct result of the manipulation. These are manifested clinically by sudden

FIGURE 4. Diagram of a Complicated Abscess.

The zone of surrounding pneumonitis is extensive. Daughter, or secondary, abscesses fail to communicate directly with the primary cavity. Bronchiectasis has developed in the corresponding pulmonary segment. Empyema may or may not be present. Note the semi-solid caseous debris that is found within the cavities.

death on the operating table, because of air embolism or other embolism; intracranial suppuration, usually brain abscess or meningitis, owing to the

The risk involved in traversing the surgical danger zone is well shown by a very critical analysis of our cases. After careful study we separated them into two groups: those in which the surgical danger zone had been traversed, regardless of the reason, and those in which this zone had not been traversed. The results are shown in Table 5. An increase in the mortality rate of 300 per cent should certainly make one exceedingly wary of manipulating the danger zone in any way. It should be

TABLE 5. Results According to Whether or Not the Surgical Danger Zone Was Traversed.

SURGICAL APPROACH	NO. OF CASES	NO. OF DEATHS	MORTALITY RATE %
Danger zone not traversed	33	3	9
Danger zone traversed	30	8	27*

*Two late deaths from the disease are not included

pointed out that external drainage of lung abscesses in the complicated stage was by far the most important single factor that forced us to traverse the danger zone. It is technically impossible to drain certain daughter abscesses without cauterizing or incising through this zone. The next most important cause of traversing the danger zone was inaccurate localization in our earlier cases.

METHODS OF TREATMENT AND RESULTS

Miscellaneous Therapeutic Measures

In the earlier cases in our group there was a tendency to employ methods of treatment, especially various types of collapse therapy and supportive measures, that were considered to be more conservative than early external drainage. Our experience with conservative treatment, including both collapse therapy and other measures, has been uniformly unfavorable. Sixteen patients were

speaking loudly against this type of treatment. It should be pointed out that the results would be much worse if many of the patients in this group who failed to improve had not finally been treated by external drainage or excision.

Lung Resection

Thirteen patients were treated by excision of pulmonary tissue, 6 by lobectomy, 3 by lobectomy in addition to subtotal excision of an additional lobe, and 4 by total pneumonectomy. The indica-

FIGURE 5 Posteroanterior (A) and Lateral (B) Roentgenograms.

Symptoms of abscess were apparent ten days after herniorrhaphy under difficult general anesthesia in a man of thirty-eight. The original area of pneumonitis and excavation involved only the apex of the lower lobe. Within three weeks there was rapid dissemination of the infection and pulmonary gangrene, with a fatal termination. Note that the suppurative process was limited to the posterior portion of the lung, which was the dependent portion, while the patient remained flat on his back. Note fluid level in lateral film.

treated primarily by various types of collapse procedures in different combinations. When one

*At the beginning of treatment there were 10 cases classified as "simple" and 9 as "complicated."

operation failed another was tried. In 11 of the 16 cases after collapse therapy had failed, additional surgery was carried out, usually after the abscess had reached the complicated stage. The results obtained in this entire miscellaneous group, including 3 patients in whom no surgical treatment was given and those treated by collapse therapy, are given in Table 6. The deplorable results

for the operations in 11 cases were extensive involvement with fibrosis, multiple isolated abscesses and well-established bronchiectasis demonstrated by lipiodol injection.

In 2 of the 13 cases it was impossible to exclude the possibility of peripheral cancer, and complete excision was deemed the safest procedure. The results are shown in Table 7.

The first postoperative death was due to sepsis following a right middle lobectomy in a man of fifty-five years of age. Excision was chosen because the lesion was suspected of being peripheral carcinoma. The next death occurred in a twenty-four-year-old woman who had had previously a two-stage thoracoplasty that failed to control a post-tonsillectomic lung abscess of the upper lobe. Owing to the previous operations, lobectomy was difficult from a technical standpoint. In addition to this, the lesion had extended from the lower lobe into the upper, which necessitated subtotal

resection of that lobe in addition to the resection of the lower lobe. The patient died four days post-operatively, because of a contralateral bronchopneumonia. The third patient also had a lobectomy with excision of part of an additional lobe for the same reason. Death occurred three days postoperatively from a spreading pneumonitis and cerebral embolism. Lobectomy and pneu-

center of the abscess cavity. The lipiodol can be seen on the final roentgenograms, and the lamp black shows up clearly at the time of operation. It is therefore possible to be far more exact in approaching the abscess cavity by establishing the relation of the underlying cavity to the suspension as seen in the x-ray films and as seen at operation. A 25-gauge needle with

*Asymptomatic but with persistent drainage from empyema

monectomy are procedures necessitated only in neglected and complicated cases. If drainage is established during the early simple stage of the disease, resection will seldom be required.

External Drainage

The success or failure of external drainage of lung abscesses depends on whether or not accurate localization has been established before the incision of the lung abscess is undertaken. This explains the failure of surgeons in the past to treat this disease successfully. They were hopelessly handicapped without the aid of adequate roentgenographic equipment. In spite of the highest degree of surgical skill, they were doomed to failure without exact methods of localization. An error of even an inch, especially in draining simple lung abscesses, frequently spells the difference between a safe incision and one that passes through free pleura or the surgical danger zone or both.

Because of the importance of accurate localization, the details of a method that we have found very helpful will be given.

Localization. The details of procedure are as follows:

Empty the cavity as well as possible by postural drainage immediately before roentgenograms are to be taken. The purpose of this is to allow air to replace fluid, so that the area of excavation may be more apparent.

Take preliminary posteroanterior, lateral and various oblique films, as determined fluoroscopically.

Review the films for preliminary localization.

Inject 2 or 3 minims of a 30 per cent suspension of lamp black in lipiodol (40 per cent iodine) just beneath the fascia of the external intercostal muscle at its junction with the periosteum of the rib that most nearly overlies the

a blunt bevel should be used to minimize the tendency of the suspension to diffuse from the point of injection.

Take final anteroposterior (or posteroanterior), lateral and oblique films—over-exposed if indicated by the preliminary films. The patient should be rotated to localize the abscess properly. We greatly prefer flat roentgenograms with varying degrees of rotation to stereoscopic films.

Operative procedure. The patient is placed in the Trendelenburg position, during operation, to minimize the possibility of cerebral emboli. In most cases the anesthetic of choice is local anesthesia after preliminary medication with Nembutal followed by morphine and scopolamine. This should be supplemented by the administration of oxygen under positive pressure before incision of the pleura, best given by means of a standard anesthesia machine with a tightly fitting face mask. The danger of bronchogenic spread during the operation is thus minimized by preserving the cough reflex and directing the flow of air toward the periphery of the lung. Positive pressure also prevents the lung from falling away from the chest wall if the pleura is opened either intentionally or accidentally.

Surgical technic. A general outline of the operative technic used at the present time is as follows (Figs. 6 and 7):

The thoracic cage is exposed over the site of the abscess, regardless of its position, and the incision is planned to strike the center of the abscess rather than its most dependent point.

The previously injected lipiodol and pigment are then located, as a guide for determining the position of the underlying abscess.

An 8-cm. to 10-cm. segment of the rib over-

lying the center of the abscess is excised, and the stumps covered with bone wax to prevent infection.

The inferior intercostal neurovascular bundle is ligated proximally and distally, and the su-

parietal pleura — by sharp dissection. From here the procedure may follow two courses:

IF A PLEURAL SYMPHYSIS IS FOUND:

Prepare the wound of the chest wall to pre-

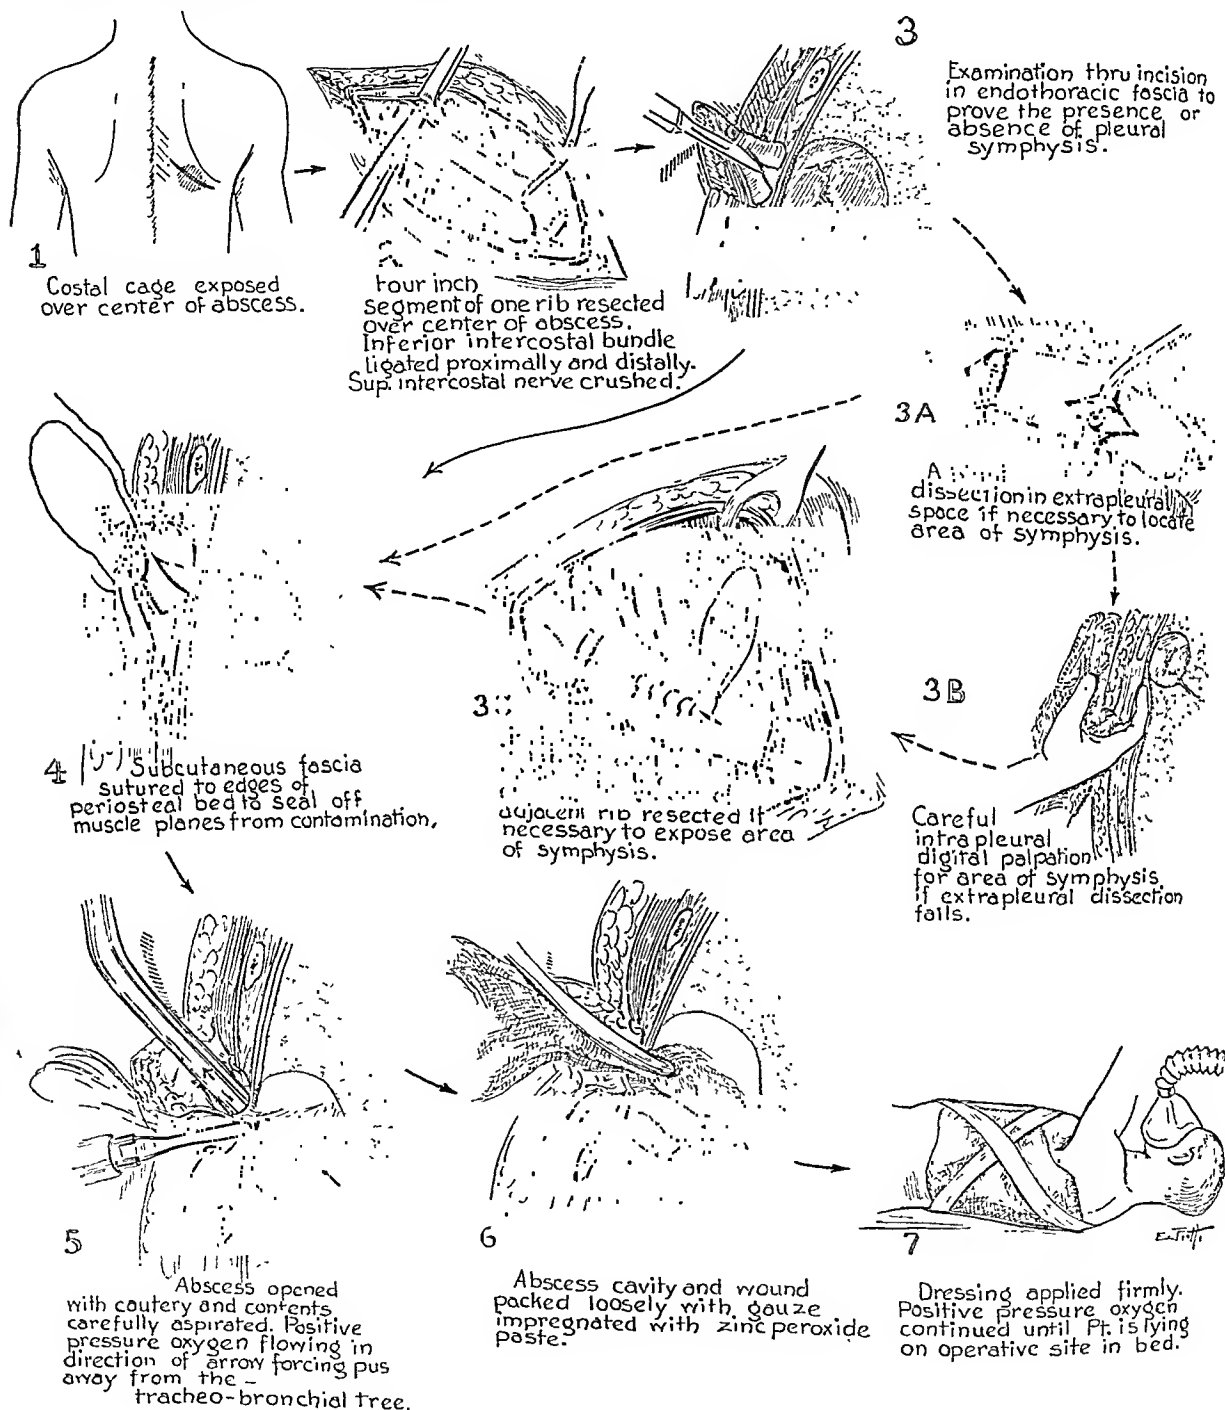

FIGURE 6. Diagram of Steps in Surgical Drainage of a Pulmonary Abscess That Points on the Costal Cage.

3A, 3B and 3C indicate alternate steps, should one fail to find the area of symphysis at the first attempt.

perior intercostal nerve crushed to decrease the discomfort of postoperative dressings.

Positive pressure oxygen is applied.

An incision is made through the periosteal rib bed and endothoracic fascia — not through the

vent dissecting infection or cellulitis. This is done by suturing subcutaneous fascia to the periosteal bed and obliterating the muscle planes (Fig. 64).

Insert an aspirating needle (17 gauge)

through the area of pleural symphysis and into the cavity. The needle should not be inserted deeply, and repeated attempts to locate the cavity should not be made.

If pus or putrid air is found, leave needle

1. Interlobar fissure carefully explored by blunt dissection thru incision in rib bed and parietal pleura to locate area of pleural symphysis.

margins of the wound and dry gauze dressing firmly with positive pressure, continued until the patient has been placed on the operated side.

If pus or putrid air is not found, review the

2. Lung margins sutured to parietal pleura and rib bed.

3. Gauze packed into interlobar fissure with metallic marker against area of pleural symphysis. Arrow indicates point at which incision will be made at second stage.

4. Wound closed with interrupted sutures. End of gauze pack protruding from lower angle of wound to allow escape of serum. Second stage incision and drainage carried out in 3-5 days.

FIGURE 7. Diagram of Steps Used in Preparing Drainage Tract for Lung Abscess Pointing on Interlobar Fissure, Mediastinum or Diaphragm.

in place as a guide and open the abscess for a distance of 1.0 to 2.5 cm., depending on the cavity size (Fig. 65); aspirate the contents and pack the cavity loosely with gauze impregnated with zinc peroxide paste; apply boric acid ointment strips to the

Recently, sulfathiazole powder has been used instead of zinc peroxide. One to 5 cm. is applied to the walls of the lung abscess cavity chest wound before the gauze packing is inserted.

localization and, if it is believed certainly that it is correct, cauterize to a maximum depth of 1 cm. over the center of the area of symphysis; if localization is questionable or if no cavity was entered after cauterization, pack with dry gauze with metallic marker in depth of wound; take additional roentgenograms to

check localization and drain the abscess as soon as its position is determined.

IF A PLEURAL SYMPHYSIS IS QUESTIONABLE OR ABSENT:

Enlarge the incision and carefully dissect for a short distance in the extrapleural space.

If the adhesions are located in the extrapleural space, reapproximate the edges of the periosteal incision; expose the parietal pleura over the center of the area of pleural symphysis by removing the necessary structures, for example, additional segments of rib or intercostal muscle, and drain through this area.

If pleural symphysis is not found by dissecting in the extrapleural plane, open the pleura, introducing the finger, and carefully palpate in all directions for the point of adherence. If it is found, mark the chest wall over the area of symphysis. Close the pleural and periosteal incision. The drainage tract in the chest wall should then be prepared over the site of adhesions, and the cavity drained. If the precise localization after exploration is uncertain, the wound may be packed with gauze containing a metal clip as a marker, and drainage may be delayed two to four days. During this interval relocalization by roentgenographic study should be done.

If the adhesions cannot be located and the abscess is thought to be pointing on the interlobar fissure, the mediastinum or diaphragm, dissect carefully along the fissure line, mediastinum or diaphragm until the edge of the area of pleural symphysis is approached. Suture the edges of the parietal pleura to the edges of the adjacent lung or diaphragm (Fig. 7). Pack dry gauze with a metallic marker into the depth of the wound against the area of symphysis. Close the wound with interrupted sutures, with the gauze pack protruding from the dependent angle. Take additional roentgenograms for localization. In three to seven days reopen wound and proceed as when pleural symphysis is found.

Results

The results of external drainage of 67 abscesses in 63 patients* are charted in Figure 8. The entire group has been divided into subdivisions; one consisting of 35 patients with simple abscesses

*Since the above study of results was made, 16 additional cases have come under our observation. Again, we have found that the patient treated during the early acute phase of the disease will recover, whereas delay in surgical drainage spells disaster. Five patients with a simple abscess treated within the first 6 weeks of their illness all recovered. Of the 12 patients treated after the 6-week period 7 recovered. One patient who had suffered from a chronic abscess for 2 years died of an embolism at operation. Eight patients with complicated lesions had had extensive pulmonary destruction. Three patients had extensive gangrene and were moribund when first seen.

and the other of 28 patients with complicated abscesses. The majority of the simple abscesses were under six weeks in duration, whereas the great majority in the complicated group were over six weeks. A comparison of the results in the two groups shows the extreme importance of avoiding delay in carrying out external drainage. All cases

FIGURE 8. *The Results of Treatment of Pulmonary Abscess by External Drainage, Grouped According to the Extent of Damage to the Lung.*

Four fifths of the simple cases were brought to surgery within the first six weeks of their development. The majority of the complicated cases were late cases.

are included, regardless of the stage of the disease, the general condition of the patient, the previous medical or surgical treatment and other factors. Obviously, if the cases treated early in our experience were excluded and only those treated by the methods now used included, the results would be expected to be much better, owing to the improvement in localization and surgical technic.

ONE-STAGE VERSUS TWO-STAGE OPERATION

The entire plan of procedure used at the present time is based solely on the principle that a lung abscess should be incised only at its most superficial point, so that the zone of pneumonitis will not be traversed in any case and so that aspiration or incision will not be made through a free pleura. Inasmuch as practically all abscesses are located superficially with overlying pleural symphysis, external drainage can be carried out safely in one stage, *provided that the abscess has been accurately localized*. Without accurate localization even a two-stage procedure is a very dangerous plan of management. Although the danger of pleural contamination is theoretically removed, the primary error in localization is not corrected, which means that the subsequent incision must be made through the surgical danger zone. Thus with this plan of treatment the operative mortality rate may be expected to increase by nearly 300 per cent, to say nothing of the high percentage of severe postoperative reactions that will occur.

garding the efficiency with which a two-stage drainage protects against the development of empyema, our results are rather surprising. In a series of 67 abscesses, 24 were drained by means of a two-stage procedure, and 43 by a one-stage operation. In the two-stage group, postoperative empyema occurred in 4 cases, whereas in the one-stage group, which is nearly twice as large, postoperative empyema occurred only twice. It should be stated, however, that most of the two-stage operations were done earlier in our experience, and the methods of localization were less exact. Making the wound for the purpose of creating an artificial symphysis is followed at times by an effusion that separates the pleural surfaces. Should it occur the purpose of the two-stage operation is defeated. Furthermore, abscesses have been known to rupture, with the production of empyema, before the second stage could be performed.

We believe that the above considerations indicate any objections to one-stage drainage based on the danger of pleural contamination. The only other objection to a one-stage operation is based on the fear of development of a serious dissecting cellulitis of the chest wall. This objection is theoretically well founded. However, in actual practice the occurrence of such infections is very infrequent. A probable explanation is that the aerobic organisms rapidly lose their invasive characteristics as soon as they are exposed to the amount of oxygen afforded by a wound that is kept widely open—especially if zinc peroxide paste is used. In the 43 cases with one-stage operations there was only 1 in which a spreading infection occurred, and this cleared up rapidly after a counterincision, 5 cm. in length, was made. In this experience we have employed measures to obliterate the fascial and muscular planes. This can be accomplished by suturing the subcutaneous fascia to the intercostal muscle bundle. In 27 cases treated in this way spreading infection from the wound edges has not occurred. The danger of cellulitis of the chest wall becomes insignificant when compared with the possibility of pneumonic spread after the first stage of a two-stage procedure. In our group of 24 cases in which two-stage drainage was planned, 2 patients died before the abscess could be drained. A similar experience is commonly mentioned in the literature. We believe that a two-stage operation has a definite and a useful place in the treatment of lung abscess. However, we also consider its usefulness to be limited to a very small group of cases, especially to those in which the abscess is pointing on the mediastinum, on an interlobar fissure without symphysis, on the costal cage, and on the diaphragm. It is

occasionally necessary when technical difficulties are encountered.

TIME OF EXTERNAL DRAINAGE

So long as early external drainage continues to produce results similar to those that it has produced to date, we shall consider that, in general, it should be carried out as soon as the diagnosis of lung abscess can be established definitely, and localization can be agreed on. To postpone external drainage is to encourage the relentless progress of the disease from the simple to the complicated stage. This means that the cure rate will drop from 94 to 26 per cent, and that the mortality rate will soar from 6 to 32 per cent (Figure 8). The rapidity with which the disease may pass from the simple stage, through the complicated stage, to death, should be emphasized so that the danger of procrastination may be fully appreciated. The studies of Rives, Major and Romano¹² also indicate the rapid course taken in many cases. In their study of 100 consecutive fatal cases of lung abscess, they found that 73 per cent classed as "frankly hopeless" were of less than one month in duration, and that 75.5 per cent of these cases were less than two months in duration. In view of these figures we are convinced that any feeling for the security of the patient with lung abscess during the first six weeks is false. The frequent statements in the literature that surgery should not be considered until the chronic stage of the disease has been reached, which usually takes from two to three months, are dangerous advice. Associated with such statements is the implication that few if any deaths will occur during this period. When this fallacy is generally comprehended, there should be much less tendency to experiment with uncertain methods of treatment.

We believe that external drainage should be performed without delay for another important reason. We fear that we shall be enticed into the dangerous game of procrastination by the intangible and irresistible human forces far past the point at which our better judgment would ordinarily tell us to stop. This fact is best illustrated by the figures of Brunn,⁹ which give the time that surgical treatment was instituted in a group of 205 cases from four institutions, three of which were teaching hospitals in San Francisco. The duration of the disease averaged four hundred and sixty days. The average duration of medical observation and treatment was one hundred and fifty-four days—twenty-eight days short of half a year!

Practically all writers on the subject have stated repeatedly that recovery from lung abscess by conservative means can rarely be expected after the duration has reached three or, at the most, four months. Still, in this group, the average duration of the disease before operation was over fifteen months, and the average duration of medical treatment in the hospitals was over five months. It is interesting to correlate the effect of this delay on the results obtained in this group (Table 2).

SURGICAL VERSUS MEDICAL TREATMENT

A very close analogy can be drawn between the history of the treatment of lung abscess to date and the early history of the treatment of appendicitis. Shortly before the turn of this century, acute appendicitis was considered by the authorities of the time to be a medical disease. The mortality and morbidity rates were high. Laparotomy at that period was feared, largely because of the results associated with this procedure during the time when its various technical obstacles were being surmounted. Therefore, conservative treatment was routinely carried out until the disease had progressed to such an advanced stage that radical surgical aid was asked for, of necessity. For reasons that are now perfectly obvious, the mortality and morbidity rates with surgical treatment were also very high. Because of this, physicians clung even more tenaciously to conservative medical treatment. Thus a vicious circle was formed, and the results of all types of treatment of appendicitis were poor. And they remained poor until such pioneers as J. B. Murphy, Reginald Fitz, J. B. Deaver and others, after a bitter and prolonged struggle against the authorities of the time, showed that, to obtain satisfactory results, surgical treatment must be instituted at an early stage of the disease, before the pernicious forces of the vicious circle are set in action.

At the present time lung abscess is generally considered to be a medical disease. The mortality and morbidity rates are high. Early external drainage is looked on with apprehension. It is feared that some patients will be submitted to unnecessary surgery. We believe that the foundation of this fear has several components, the main one being the unfavorable results obtained by this procedure without exact preoperative localization of the abscess. Because of the general fear of surgical treatment the so-called "conservative measures" are routinely carried out until they are proved to be inadequate, and the patient's life is threatened. Surgical aid is applied after irreparable damage to the lung has occurred, and the results are necessarily poor. Because of this, the general tendency is to cling even more tenaciously to the

temporizing medical measures. Again a vicious circle has been formed, which, like a whirlpool, continues to take a high toll in life and health from the unfortunate victims who drift into its irresistible influence.

We firmly believe that the only way to obtain a low mortality rate and a high cure rate in the treatment of lung abscess is to employ early external drainage after accurate localization. Inasmuch as lung abscess is a relatively uncommon disease, we are very much concerned about how long it will take to break the vicious circle that now exists and bring early external drainage into general acceptance. Even though appendicitis was and is a very common disease, it took many years and countless debates at medical gatherings to change the status of its treatment from being primarily medical to primarily surgical. Let us hope, for the sake of the welfare of all future patients who suffer from pulmonary abscess, that the present battle that is in progress in regard to proper management will be soon settled. The problem resolves itself to one of numbers and facts.

CONCLUSIONS

The separation of abscesses into acute and chronic stages on a purely chronological basis without regard to the pathologic condition present is unscientific and unsatisfactory. From a practical standpoint it has given rise to a great deal of confusion in evaluating the results of different therapeutic measures. We suggest that this commonly used chronological division be replaced by a classification based on pathology.

It is proposed that lung abscesses be separated into their simple and complicated stages. The simple stage includes a single or a multilocular cavity without secondary bronchiectasis. Complicated abscesses consist of multiple isolated daughter abscesses located in the surrounding zone of pneumonitis, which do not connect with the primary cavity and do not point on the surface of the lobe. In this group we have also included patients who have developed an associated bronchiectasis or empyema.

Lung abscesses are almost invariably situated peripherally with relation to the lobe in which they are located. Therefore, early symphysis between the adjacent pleural layers practically always occurs.

Roentgenographic evidence of cavitation is not essential in establishing the diagnosis. Not infrequently a patient with abscess of the lung will pass through the entire course of the disease to a fatal termination without presenting evidence of definite cavitation.

The generally accepted plan of combined medical and surgical treatment of abscess of the lung continues to keep the mortality over 30 per cent and the cure rate under 50 per cent as shown conclusively by statistics.

In the group of patients treated by us for both simple and complicated lung abscess by miscellaneous methods other than excision or external drainage, the results obtained were poor. The mortality rate was 53 per cent, and the cure rate 26 per cent.

External drainage of complicated lung abscesses has an operative mortality rate of 32 per cent and a cure rate of only 26 per cent.

External drainage of simple lung abscess has an operative mortality rate of 6 per cent with a cure rate of 94 per cent.

The outstanding factor in the development of a complicated from a simple lung abscess is time. Most simple lung abscesses are of less than six weeks' duration. Most complicated lung abscesses are of more than six weeks' duration. Therefore, delay of external drainage, regardless of the reason, parallels directly the bad results obtained. The longer the delay, the worse the results.

Methods of treatment based on internal drainage of the cavity fail because of the small bronchi that lead from it, which provide neither adequate drainage nor adequate aeration of the cavity. These two fundamental factors must be satisfied before healing will occur.

The most important single factor in causing failure of methods based on internal drainage is the presence of semisolid slough or inspissated caseous debris inside the abscess cavities. This precludes the possibility of firm healing and accounts for frequent recurrences.

Intrathoracic spread of the disease is the major cause of death of approximately 85 per cent of patients treated by conservative methods. By far the most important causes of intrathoracic spread are inadequate drainage, faulty aeration of the cavity and any factor that promotes bronchogenic spread of the pus throughout the tracheobronchial tree.

We have outlined in detail the methods of surgical approach, which we believe to be based on sound principles and practical application. The dangers of traversing normal lung tissue or the zone of pneumonitis that surrounds the cavity have been emphasized. With accurate localization one-stage drainage is not only possible but also definitely safer than two stage drainage in the majority of cases.

Lung abscess should be considered a surgical disease from its onset, and early drainage should

be instituted without delay. The provision for external drainage during the simple stage of the disease is the only type of treatment, to date, that has uniformly yielded a high cure rate and a low mortality rate.

DISCUSSION

DR. EDWARD D. CHURCHILL, Boston: A paper on lung abscess always offers a real challenge to those of us who are interested in thoracic surgery, and I am glad to be afforded the opportunity to comment on Dr. Overholt's contribution. Statistical studies on lung abscess at the Massachusetts General Hospital go back to 1909. Dr. Lord in 1925 analyzed the results in 227 cases collected between 1909 and 1924. Two hundred and eleven cases recorded between 1924 and 1932 were reported by Lord and King. This year, Dr. Sweet¹³ has published an analysis of 125 cases observed during the five year period, 1933 to 1937 inclusive. As a result of these studies we have a stable definition of lung abscess for purposes of classification, and unfortunately for our own peace of mind, an exact record of what we have accomplished in the therapy of this disease.

Our best results are recorded in the recent analysis by Sweet of 124 consecutive cases. Sixty-one patients, or 49 per cent, were cured; 42, or 34 per cent, died; and 21, or 17 per cent, remained alive with disease. These figures deal with all cases, early and late, complicated and uncomplicated, ably handled and grossly neglected before entering the hospital.

In the entire group of 124 cases only 8 patients came to the hospital soon enough after onset for drainage to be carried out before the end of the sixth week, so that in general this group is comparable to the "complicated" group of Dr. Overholt's in which he places "four fifths" of his cases that were over six weeks' duration and in which he records a mortality of 32 per cent and a cure rate of 26 per cent.

Now we come to the real challenge offered by this pa-

per. Dr. Overholt states that "external drainage of a simple lung abscess has an operative mortality rate of 6 per cent with a cure rate of 94 per cent." Because "four fifths" of the abscesses classified as "simple" were subjected to external drainage within six weeks of onset the conclusion is drawn that "external drainage should be carried out as soon as the diagnosis of lung abscess can be established." If the figures support this conclusion, a specific remedy has been found for a devastating disease that hitherto has carried a mortality rate of 34 or more per cent. When so important an announcement as this is made, the author invites a very critical survey of his documentary evidence.

The series of 35 cases of "simple" abscesses were apparently selected nonconsecutively from a larger group that includes the "complicated" cases. "Approximately four fifths" of the 35, that is, 28 cases, were subjected to external drainage within six weeks from time of onset. It is to be noted, however, that 5 or 6 other cases (one fifth of the group of 28 "complicated" cases) were also subjected to external drainage within six weeks of the date of onset. They are placed in the "complicated" group, in which the group mortality is given as 32 per cent, but no specific information is given regarding the fate of these 5 or 6 patients, in whom we are intensely interested.

We may therefore conclude that Dr. Overholt has drained lung abscesses of less than six weeks' duration in 34 (28 plus 6) patients. Two patients (6 per cent of 35) in the "simple" group died, and lacking information to the contrary, let us assume that all 6 in the "complicated" group died. This gives a mortality of 8 out of 34 or 23 per cent for cases drained under six weeks.

This line of investigation can be carried further. There is no note of spontaneous cures. During two successive five-year periods our spontaneous cure rate has been 21.4 per cent and 19.3 per cent respectively. If it is assumed that 20 per cent of Dr. Overholt's early abscesses would have subsided spontaneously if allowed to do so, it is permissible to state that 7 cases were operated on as a prophylactic measure and proceeded to get well, as they would have done without operation. Subtracting 7 cases from the total of 34, leaves but 27 cases in which external drainage as a curative measure was necessary. Eight of these patients may have died, as already noted—a mortality rate of 30 per cent. Dr. Sweet has shown in an

ingenious table that a patient with an abscess of six weeks' duration faces a mortality rate of 28.9 per cent. A remarkable coincidence!

I know that I have been hypercritical and also quite possibly unfair, particularly in assuming that all 6 patients operated on early and placed in the "complicated" group died. However, it is not sound reasoning to conclude that abscesses should be drained as soon as the diagnosis is made on the basis of results in a selected group of simple abscesses.

So much for the statistical evidence. Another phase of the paper puzzles me a great deal. Within six weeks of onset Dr. Overholt has arrived at a diagnosis of lung abscess and proceeded with external drainage in 34 out of a total of 94 cases during an eight-year period. At the Massachusetts General Hospital the diagnosis has been made and the patient admitted to the hospital under six weeks in but 8 cases out of a total of 124 in a five-year period. I have always thought that in New York Dr. Neuhof might have an unusually alert and well-informed group of medical associates to provide him with his material, but Dr. Overholt brings the problem closer home. Is it possible that we are working with different definitions of lung abscess and that our clinical material is not comparable for this reason? This cannot be judged until Dr. Overholt presents a more detailed account of the patients operated on within six weeks—an account that lists age, sex, location of the abscess, x-ray findings, and particularly etiology.

I find myself in accord with one very important conclusion of Dr. Overholt's paper, a conclusion that should not be overlooked in a squabble about details. The non-operative treatment of lung abscess in the community as a whole is being continued far beyond the point where any reasonable chance for spontaneous cure has passed. Irreparable damage to the lung results, and when surgery is called for, a more radical procedure than external drainage must be employed.

It is not possible to determine by any rule-of-thumb method just when a reasonable expectation of spontaneous cure ceases. This can be judged in the individual case only by careful clinical and laboratory observation, and as a result of experience in the management of the disease. A sound knowledge of the pathology of lung abscess makes it unnecessary to try this or that newly proposed remedy to know whether or not it will work.

REMOVAL OF IODIZED OIL BY LUMBAR PUNCTURE

CHARLES S. KUBIK, M.D.,* AND AUBREY O. HAMPTON, M.D.†

BOSTON

BECAUSE of its irritating effects, there has been an increasing tendency to forego the use of iodized oil in myelography and to employ the

surgical condition is present, and the reluctance to use iodized oil under such circumstances is often responsible for prolonged disability of patients

FIGURE 1.

Roentgenograms before (A) and after (B) removal of iodized oil, injected into the lumbar subarachnoid space four days before removal. Small amounts of oil remain in the cul-de-sac and in the sheaths of the nerve roots. The dense shadow represents the hilt of the lumbar-puncture needle, inserted between the third and fourth lumbar vertebrae; the heavy transverse line, a needle on the surface used as a marker.

less reliable procedure of pneumomyelography. If the oil can be removed shortly after its introduction, as may be done when it is accessible at operation, there is no serious objection to its use. One cannot always be certain, however, that a

who might be relieved by surgery. This is particularly true when a ruptured lumbar intervertebral disk is suspected but the history and findings are inconclusive. By the use of iodized oil it can be determined, almost without exception, whether or not a ruptured disk is present, whereas a pneumomyelogram still leaves one in doubt.

We are, therefore, submitting a simple method

*Instructor in neurology, Harvard Medical School, neuropathologist and assistant neurologist, Massachusetts General Hospital.

†Instructor in roentgenology, Harvard Medical School; roentgenologist, Massachusetts General Hospital.

for the removal of iodized oil from the lumbar subarachnoid space.

After the roentgenographic examination has been completed, the patient is placed face down, horizontally, on a fluoroscopic table; the iodized oil is visualized; with the patient still in the prone position, a lumbar puncture is made in the space beneath which the oil is located. The oil, or the greater part of it, is then withdrawn by gentle suction with a small syringe. By tilting the table, un-

An ordinary 18-gauge lumbar-puncture needle is entirely satisfactory; oil introduced only a few hours previously and still very nearly in its original, thick, viscid state can be removed through it without difficulty. When, on the day following introduction or later, the oil is emulsified, it flows more easily, but if it has entered the sheaths of the nerve roots, some of it may not be recovered. We believe that a few globules of oil left free in the lumbar cul-de-sac are of little or no im-

FIGURE 2.

Roentgenograms before (A) and after (B) removal of iodized oil, injected five hours before removal. A few droplets of oil remain in the cul-de-sac. The lumbar-puncture needle was inserted between the third and fourth lumbar vertebrae.

der fluoroscopic control, any remaining oil is brought to the point of the needle and removed. Since small droplets of the oil may not be visualized with the fluoroscope, a film is taken before the needle is withdrawn, to make sure that removal of the oil has been as complete as possible.

A few comments may be added. Before performing the lumbar puncture the table is tilted 20° or so, raising it at the head end, to distend the lumbar cul-de-sac. Then the table is leveled again, bringing the oil back to its original position, or centered round the needle, the point of which should be in the ventral portion of the subarachnoid space. If suction is too strong, pain may result and the flow of oil may stop, presumably because a nerve root or fold of membrane has been drawn against the point of the needle. Using less force and turning the needle overcome this difficulty, which is not very serious and is more likely to occur when the needle, in being inserted, has deviated too far from the mid-line.

portance, although with a little persistence all of it can be removed. Needless to say, the discomfort and incapacity suffered by the patient are insignificant.

Since the above procedure results in more complete removal than is usually possible at operation, it may be used with advantage, if the oil is accessible, even when there is to be an operation later. Another reason for preoperative removal in cases of ruptured lumbar intervertebral disk is that it obviates incision of the meninges, with resulting loss of spinal fluid and unnecessary exposure of the subarachnoid space to infection. The method may also be employed in suitable cases of suspected compression of the cervical or thoracic cord by introducing the oil into the lumbar subarachnoid space instead of the cisterna magna.

We have used this procedure in over 30 cases. It is most effective when the needle is inserted through the third or fourth lumbar interspinous space, although complete removal has been ac-

completed through the second and, on one occasion, the first lumbar space. One obviously tries to avoid the suspected lesion.

It is important to make a neat puncture so that the point of the needle will be near the mid-line, to use no more suction than is necessary to bring the oil very slowly up into the syringe, and not

to continue or, what is worse, increase strain on the needle is blocked. The needle in Figure 1 is badly placed.

For some time we have been introducing the oil with the patient on the fluoroscopic table, leaving the needle in place during the examination, and removing the oil immediately afterward.

THE AUTONOMIC NERVOUS SYSTEM PRIOR TO GASKELL*

DONAL SHEEHAN, M.D.[†]

NEW YORK CITY

IN a charming tribute to his former teacher, Langdon-Brown¹ (1939) writes provocatively that "to read an account of this [autonomic nervous] system before Gaskell is like reading an account of the circulation before Harvey." During a recent search through the writings of physiologists just prior to Gaskell and Langley, I had the opportunity to ponder this statement and to wonder why so many threads of evidence lay unrecognized until these two men, so curiously different in temperament, began to weave them into the pattern of the visceral nervous system as we know it today. The osmic acid technic, then recently introduced by Schultze, no doubt enabled Gaskell to see the fibers of the autonomic nerves in much clearer outline, but one should not attach too much importance to this factor, since the Weigert method of staining myelinated sheaths had often been used before in studying the constitution of the ventral spinal nerves and, indeed, of the rami communicantes. Gaskell² built his theory on two main lines of evidence: that only the ventral roots in the thoracolumbar and sacral regions contained fine myelinated fibers, and that these fibers were present only in the white rami that were limited to the same regions ‡ It is interesting that although true as generalizations, both observations proved to be inaccurate in the light of subsequent investigation. Nevertheless they gave Gaskell the due to a new understanding of the construction of the autonomic nervous system. The difference between the thoracoventral roots and those elsewhere had been noted as early as 1862 by Reissner,³ and it must have been seen by many others, un-

doubtedly by the great Henle⁴ and by ~~the~~ without their appreciation of its underlying ~~importance~~ cance. There can be little doubt ~~that~~ possessed a quality of genius that ~~not only to see but also to comprehend~~

In like manner, the effect of nicotine on autonomic responses, described by Langley,⁶ gave to Langley another new which to attack an age-old problem. He did not overlook the fact that it was in collaboration with Dickinson, shown to act by interrupting the synapse in the sympathetic ganglion, a fact that was in Langley's approach. Nor can one say that Langley's genius demanded of him a patient and meticulous search, which is that, in the words of Fletcher,⁷ "it is only in their places not merely there to knowledge, but as stones along which, at the progress of knowledge has a

In looking for the germ one is tempted to turn at once to the man who so often predicted the event day. Prior to Bernaretti's nervous system was a wealth of theoretical and factual knowledge. To the sympathy of the "intelligent" proved in 1727 by Pelletier, its constituent fibers were in 1838 by Remak, innervated fibers, as Hermann,¹² who found fibers as sympathetic were little independent between the cerebellum and there had been they communicate.

⁴From the Department of Anatomy New York University College of Medicine

[†]Professor of anatomy and director of anatomical laboratories New York University College of Medicine

to Gaskell apparently counted fifteen instead of thirteen thoracic nerves in the dog so that the subsequent lumbar and sacral nerves in men and dogs might have the same numbering. Thus he gave 15 the lower limit of the thoracolumbar outflow in the dog; the twenty-fifth spinal nerve which he called L2, instead of L4 as it is customarily designated. This rather unfortunate method of numbering led to considerable confusion in subsequent interpretation.

nal roots or both (Müller,¹³ Retzius,¹⁴ Wützer¹⁵). Beck,¹⁶ in 1846, was probably the first to point out that the white rami consist of myelinated (tubular) fibers that emerge from the spinal cord, and that the grey rami contain unmyelinated (gelatinous) fibers arising within sympathetic ganglia, probably in connection with the cells described earlier by Ehrenberg.¹⁷ I¹⁸ have already reviewed this early phase in the literature, and the following remarks on the period just prior to Gaskell should be considered as supplementary to that paper.

It was apparently Senac¹⁹ who, in 1794, first discussed the contractility of the blood vessels in relation to the sympathetic nerves, which he described as embracing the larger arteries and sending fibers along their finest ramifications. Certainly Petit²⁰ in 1727 and subsequently Cruikshanks²⁰ (1795), Arneemann²¹ (1797) and Reid²² (1838-39) had noticed a redness of the conjunctiva after section of the cervical sympathetic ganglion, but they did not appreciate the significance of their observation, nor did Dupuy²³ (1816) and Brachet²⁴ (1837), who described the same "inflammation" of the conjunctiva and an elevation of skin temperature on the ipsilateral side of the face after extirpation of the superior cervical ganglion. Brachet came nearest to the present concept of vasomotor tonus when he remarked that the "inflammation" was not an excitatory effect but an atony or paralysis. Then came the irrefutable demonstration by Henle,⁴ in 1840, of muscular elements in the walls of blood vessels. Before the work of this histologist, the middle coat of the arteries had been designated by different authors as the "muscular tunic," but the term had been purely visionary. Physiologists who had upheld the contractility of vessels had to suppose the presence of muscle in their walls and by happy inspiration had placed it in the tissues of the middle coat. Henle's description and its confirmation in 1849 by Kölliker⁶ removed all doubt about both the arteries and the veins, and the authors did not hesitate to attribute to the nervous system an action on the muscular wall of the vessels. Although experimental proof was lacking, the idea must certainly have been in the minds of physiologists during the first half of the nineteenth century, for in 1840 Stilling²⁵ proposed the substitution of the term "vasomotor system" for the name "sympathetic." The ground was well prepared for the experimental work of Schiff,²⁶ Claude Bernard⁹ and Brown-Séquard²⁷ that provided the proof for the existence of vasomotor nerves. The story of this is so ably told elsewhere (Fulton²⁸) that it need not be dwelt on any further.

The demonstration that such vasomotor fibers

emerge from the spinal cord followed logically Budge and Waller's²⁹ account in 1851 of the pupillary fibers in the lower cervical and upper thoracic regions of the cord and passing out in the cervical sympathetic.* "One of the great merits of the experiment of Budge and Waller," wrote Bernard,⁹ "is that it showed for the first time in an incontestable way that the fibres of the great sympathetic take origin from the spinal cord." And following this line of reasoning, Bernard cut the ventral and dorsal roots of all the nerves that supply fibers to the brachial or the lumbosacral plexus, without causing any change in vascularity or temperature in the corresponding paralyzed and anesthetic extremity. It mattered little whether the ventral or dorsal roots or both were divided. Therefore, concluded Bernard, the vasomotor nerves to the extremity do not arise in the spinal roots that furnish the motor and sensory fibers to the limbs. When, however, he divided the nerve trunks of the plexuses (brachial or lumbosacral), there appeared in addition to the motor and sensory loss an immediate rise in temperature of several degrees in the corresponding foot. This proved that the vasomotor fibers join the motor and sensory nerves to the extremity outside the vertebral canal, and Bernard's attention was naturally attracted to the sympathetic chain. The next logical step was the removal of the stellate ganglion, or of the lumbar sympathetic chain lying on the bodies of the fifth and sixth lumbar vertebrae, and Bernard then obtained the rise in temperature without the motor or sensory changes. Stimulation of the sympathetic chain had the opposite effect of reducing the circulation and lowering the temperature in the limb. The proof of independent vasomotor fibers was therefore complete, but, curiously enough, Bernard did not push the matter further, and the tracing of the exact outflow of the fibers from the cord was left to others. In a significant passage, however, he comments:

It seems to me that sometimes the temperature changes in the posterior extremity followed stimulation of the regions of the spinal cord higher up [than the origin of the lumbosacral plexus], and I have seen an increase in temperature in the anterior extremity and in the ear on cutting the sympathetic chain at the level of the third and fourth intercostals, without any accompanying ocular phenomena.

Thus Bernard predicted that the outflow of the vasomotor fibers would be found in the region of

*Budge²⁹ relates that Petit made his first experiment in Namur in 1712, and later (in 1725) repeated it before Winslow, Senac and Hunant in Paris. Petit had demonstrated myosis on section of the cervical sympathetic, but Biffi,²¹ in 1846, was the first to show that stimulation of this nerve caused dilatation of the pupil. The experiment was repeated by Waller in Bonn, where Budge was then working; thus in 1851 the collaboration of Waller and Budge on the innervation of the iris began.

the spinal cord between the cervical and lumbar enlargements.

The account of the vasomotor nervous system written by Vulpian³² about the time of Bernard's death, and more than a decade before Gaskell's classic paper, reveals an extraordinarily modern outlook. The rami communicantes were by this time fully understood. They were composed of two groups of fibers, one traveling from the spinal cord chiefly along the ventral roots, the other arising in the ganglia and running to the periphery. The vasomotor nerves along their course from the cord to the blood vessels were therefore believed to communicate with one or more sympathetic ganglia. In 1877-1878 Luchsinger,³³ having confirmed Goltz's³⁴ observation that stimulation of the sciatic nerve caused sweating on the corresponding foot, established the existence of true sudomotor fibers in the sympathetic nerves, and proved by stimulation experiments in the cat their emergence from the spinal cord, to the leg from T10 to L4 inclusive and to the arm from T3 to T6 inclusive. Thus the physiologists began placing first the vasomotor, then the sudomotor and ultimately the pilomotor fibers within the thoracolumbar outflow as we know it today, and as early as 1884 Dastre and Morat³⁵ wrote: "From the anatomical standpoint there is a remarkable arrangement, for the sympathetic appears to arise principally from the thoracic region." The authors added, "One can assign to the sympathetic centers a distinct position in the cord, in a chain of ganglionic tissue occupying the outer angle of the anterior horn and known as the tractus intermediolateralis."

In like manner, Bernard,⁹ Schiff³⁶ and Vulpian³² had shown the existence of vasodilators in certain of the cranial nerves,—the chorda tympani and glossopharyngeal nerves in particular,—and Eckhard³⁷ in 1863 had demonstrated a sacral outflow of vasodilators in the nervi erigentes. The relation of the vagus nerve to the "organic" nervous system had been established in 1846 when the Webers³⁸ showed its inhibitory cardiac effect, and the cranial ganglia, the ciliary, sphenopalatine, submaxillary and otic, had all been described and regarded as belonging to the ganglionic nervous system by Arnold³⁹ in 1827. Meanwhile the embryologic studies of Schenk and Birdsall,³⁹ of Balfour,⁴⁰ and particularly of Onodi⁴¹ had given final proof of the spinal origin of the sympathetic trunk.

Thus, as in Bernard's discovery of the vasomotor nerves, the ground was well prepared for Gaskell. This in no way belittles the greatness of his contribution, for we have but to turn to a work similar to his that appeared two years earlier

to see how differently the same data could be interpreted. Schwalbe⁴² had been interested in a proposition that the diameter of a nerve fiber might vary directly with its length, and he therefore examined the ventral roots of several cervical and thoracic nerves in man. Observing that the cervical roots contained only a few fine fibers, whereas in the thoracic roots there were numerous bundles of fibers of 18 to 27 microns in diameter, Schwalbe unfortunately argued that the predominance of small fibers in the thoracic nerves was owing to the fact that they had a shorter course to the periphery than the cervical nerves extending into the arm. Indeed it was some years before the magnitude of Gaskell's advance was appreciated, even by those working in the same field, as is evident from Kolliker's involved account of the sympathetic nervous system in 1894.

To Gaskell, then, must be given the credit for the discovery of the thoracolumbar and craniosacral outflows, although perhaps the story as related here may not fully substantiate the commentary of Langdon-Brown, quoted at the beginning of this article. But to quote again from his delightful paper, "the splendid accuracy of Langley's mental microscope extended and completed the discoveries made by the great sweep of Gaskell's mental telescope," and in illustration of this I call attention to that extraordinarily prophetic statement of Gaskell's² written in 1886

The evidence is becoming daily stronger that every tissue is innervated by two sets of nerve fibres of opposite characters so that I look forward hopefully to the time when the whole nervous system shall be mapped out into two great districts of which the function of the one is katabolic, of the other anabolic, to the peripheral tissues two great divisions of the nervous system which are occupied with chemical changes of a synthetical and analytical character respectively, which therefore in their action must show the characteristic signs of such opposite chemical processes

SUSCEPTIBILITY TO AND LATENCY OF POISON-IVY DERMATITIS*

ROBERT J. REUTER, M.D.† AND SEYMOUR J. WHITE, M.D.‡

BOSTON AND LAWRENCE, MASSACHUSETTS

SINCE there is considerable difference of opinion about the individual susceptibility to and the period of latency of poison-ivy (*Rhus radicans*, L.) dermatitis, we carried out a series of tests on a group of 23 volunteers.

Knowles et al.¹ found their percentage of reactors to the patch test (50 per cent in 1938 and 40 per cent in 1937) definitely less than that reported by Spain² (65 per cent), by Deibert and his associates³ (59 per cent) and by Straus⁴ (76 per cent). They observed a quicker response to the leaf itself than to any of the solutions employed. The period of latency in their 56 patients tested with the leaf varied from twelve hours to over one hundred and twenty.

McNair⁵ states:

Fontana [in 1795] found the period of latency to be three, four and six days. Van Mons, in 1797, found it

to be from eight to ten days; Horsfield, in 1798, stated that the period of latency varied from a few hours to several days . . . Dakin (1829), one to three days; Bussey (1873), seven days; White (1873), generally less than forty-eight hours but sometimes five days; Park (1879), from a few hours to a few days, generally from thirty-six to forty-eight hours; Cundell-Juler (1883), about twenty-four hours; Morrow (1887), from several hours to four or more days; Pfaff (1897), . . . as long as four days; Conner (1907), often within twenty-four hours.

In 18 cases, McNair noted that the period of latency varied from one to eight days.

A poison-ivy plant was potted and maintained fresh for the experiment. All the original tests were carried out in the early spring within an interval of two weeks. A fresh and previously untouched leaf was removed from the plant at the time of each experiment. A section 2 cm. square was cut from the leaf and rubbed immediately with moderate friction for approximately thirty seconds on two skin areas, one on the flexor surface of the forearm and the other on the lower leg. A dry dressing was applied, and the subject

‡Assistant in dermatology, Boston City Hospital; associate, Lawrence Clinic.

was instructed not to wash the areas inoculated until permission was granted. Daily observation was made of the inoculated areas.

Of 3 subjects who presented no reaction at the end of one month, 2 were retested. The same

†Reinoculated, with similar result.

‡History of previous attacks of poison ivy dermatitis.

method was repeated, except that the leaf was rubbed energetically on the skin—in an area previously untouched—until bleeding points had formed, after which small bits of the leaf were strapped to the skin areas for twenty-four hours.

The persons thus tested were of both sexes and were all between twenty and thirty years of age.

There were approximately equal numbers of Anglo-Saxons, Italians, Irish, Armenians and Jews. The skins of all those tested were neither excessively dry nor seborrheic.

The results were as follows (Table 1). Twenty of the 23 subjects gave a positive reaction. Of these, 15 reacted to the first known exposure. The shortest period of latency was one day, the longest eighteen days and the average six days. The duration of the reaction varied from two to twenty-one days. The cases of shortest incubation and most marked reaction were usually those of longest duration as well.

There were no apparent variations according to sex, race or site of inoculation.

Whereas one of the darker-skinned subjects (Case 4), had a long period of latency and a very mild reaction another (Case 9) had a short period of latency and a marked reaction.

The two subjects who showed immunity, even after the second test, were Jewish, and fair of skin. One perspired profusely, with an otherwise normal skin; the other had a skin in no way different from the other subjects tested. Neither had ever experienced an attack of poison-ivy dermatitis.

CLINICAL NOTE

A SIMPLE MICROMETHOD FOR THE DETECTION OF ACETONE IN URINE

JACOB BREM, M.D.*

WORCESTER, MASSACHUSETTS

THE usual tests for acetone in the urine are the Legal test¹ and such modifications as those of Jackson-Taylor,¹ Lange² and Rothera.² A modification³ of the Rothera test employs a powder derived from a mixture of ammonium sulfate and sodium nitroprusside. All these tests require several cubic centimeters of urine and have sodium nitroprusside as their principal reagent. In the test to be described, only a few drops of urine are required, and the entire procedure is simplified.

The principal reagent for this test is a 5-gr. (0.35-gm.) tablet† made from a mixture of 1 part of finely powdered sodium nitroprusside and 40 parts of ammonium sulfate. The tablets are stable.

For the test, a tablet is placed on a white porcelain tile or dish. Three drops of urine are then placed on the tablet, followed by two drops of concentrated ammonium hydroxide. If acetone is present, a purplish color appears at the periphery of the tablet within thirty to sixty seconds, and becomes maximum within three to five minutes. After five minutes, the color tends to change to

*Assistant in pediatrics, Tufts College Medical School.

†Obtainable from Brewer and Company, Incorporated, Worcester, Massachusetts.

brown. For this reason, the test should be read at the end of five minutes.

In comparing this test with the usual macromethods, predetermined amounts of acetone were added to normal urine, and the tests were done simultaneously. In the higher concentrations of acetone, there was complete agreement of the two methods, but when the concentration of acetone became low, the micromethod was noted to be slightly more sensitive. For example, when the concentration of acetone in the urine was 0.02 per cent, a clearly positive reaction was noted with the micromethod, whereas the reaction was equivocal with the macromethod.

This test is an improvement on the macromethod because it is simpler and involves fewer steps and less apparatus; it can be performed on very small amounts of urine—3 to 4 drops instead of 3 to 4 cc.; it is timesaving, because many such urine tests can be set up and done simultaneously; it is more economical because it saves on reagents; it is as accurate as the macromethod and slightly more sensitive with low dilutions of acetone.

MEDICAL PROGRESS

POPULAR MISCONCEPTIONS PERTAINING TO OPHTHALMOLOGY

DAVID G. COGAN, M.D.‡

BOSTON

PROGRESS consists not alone in the appreciation and utilization of newly discovered facts but also in the realization and correction of prevalent misconceptions. Although the majority of misconceptions pertaining to ophthalmology are not serious in the sense that they interfere with medical practice, they are, in view of their universality, the source of unnecessary health precautions and of a not inconsiderable economic waste. So far as health is involved, it is the privilege and obligation of the medical profession, presumably the most qualified judge, to exercise its authority.

ILLUMINATION

The beliefs that relatively intense illumination is necessary for visual efficiency and that weak

illumination induces organic disease of the eyes are probably the most widely held misconceptions pertaining to ophthalmology. This is represented in the following quotation from a semiscientific treatise: "Improper lighting conditions and the misuse of light and the eyes are so effective in causing eyestrain and permanent injury to the eyes."¹

The public has been subjected to a "research offensive"² in matters of illumination, aimed toward the development of a widespread consciousness of lighting. As a result, there has been a "newborn confidence [that] increases interest and decreases resistance on the part of the user of light and lighting."³ The nucleus of this movement is in the Incandescent Lamp Department and the Lighting Research Laboratory of the General Electric Company from which have come an impres-

‡Assistant professor of ophthalmic research, Harvard Medical School; assistant surgeon, Massachusetts Eye and Ear Infirmary.

sive number of technical and popular books and pamphlets by Luckiesh, Moss and their collaborators. These authors claim to have established a new science "born of radically new concepts,"² the science of seeing. This science transcends the usual ophthalmologic and optometric practices, which "seek primarily to correct ocular defects rather than to prevent them."¹ According to this new creed, the optimal amount of artificial light is said to be far in excess of that now prevailing in "a half seeing world,"¹⁵ and thanks to the researches of this science, the "deeply hidden effects of seeing which are unnecessarily wasting human resources are at last revealed."⁶

The foundation of this science of seeing is both philosophic and experimental. Philosophically, it is based on the assumptions that man evolved in sunlight and that the aim of artificial lighting should be to produce indoor illumination intensities "competing with daylight."⁷ Although the increase in lighting intensities necessary to produce these allegedly ideal conditions amounting to thousands of foot-candles are as yet impractical,⁸ the sponsors of these ideas advocate a compromise — one that, they assert, further technical advances in lighting may make temporary only. Needless to say, the recommendations of this science, even with the compromise allowance, have come as a considerable surprise to those familiar with man's ability to adapt himself to dark, and to those who are acquainted with previous reports showing that 10 foot-candles are adequate for ordinary purposes, and not more than 20 foot-candles for exceptionally fine work.^{9, 10}

The experimental data that, according to Luckiesh and Moss, have given rise to the "revolutionary"¹¹ concepts of the science of seeing are derived from two sources: first, from observations with the Luckiesh-Moss visibility meter, which allegedly indicates in foot-candles the intensity of light necessary for any visual task; and secondly, from a number of biologic changes that the authors claim to have correlated with ease of seeing.

The measurements with the visibility meter consist in interposing between observer and test object a variable filter. The test consists in resolving two vertical bars while the total illumination reaching the eye is varied by means of the filter.¹² Of course, the same result, so far as illumination is concerned, might be obtained simply by varying the intensity of light on the test object. The visibility meter, however, does something else: it introduces another variable through the progressively increasing scatter or fogging effect of the filter. To overcome this combined result of re-

duction in intensity and increase in fogging, the authors quite naturally find that high degrees of illumination on the test object are necessary. They are, in fact, led to conclude that intensities of 100 foot-candles are desirable for ordinary reading.^{13, 14} Wholly aside from the fact that the artificial conditions set up have no common counterpart in Nature, the authors have used visual acuity as a measure of visibility, a criterion that has been uniformly shown by many investigators, although not mentioned by Luckiesh and Moss, to reach a maximum at about 10 foot-candles.¹⁶ It is somewhat astonishing that these authors, who contend that it is "necessary to reveal the shortcomings of loose statements or dogmatic opinions,"¹⁶ should show such a patent disregard for the relevant though contradictory experiments of others. Because of the unnatural conditions set up by the visibility meter and because its recommendations are contradictory¹⁷ to almost all previous pertinent investigations, it cannot be accepted as a valid test without other convincing evidence.

The other source of experimental data that is said to prove the necessity of light intensities considerably in excess of present conditions is the alleged correlation of different illuminations for reading with certain biologic changes. Specifically, the authors state that reading under low illumination produces increased tension of the finger on a push button,¹⁸ increased size of pupil,¹⁹ slowing of heart,²⁰ decrease in amplitude of convergence,²¹ increased frequency of blinking,²² and more recently, changes in the rate of reading.²³ Some of the data have been misinterpreted by the authors,²⁴ and some have been contradicted by the work of others.²⁵ None of the experiments are above controversy, and all are done with the wide intensity variations of 1, 10 and 100 foot-candles, — in some experiments 0.1 and 10 foot-candles only were used, whereas in others only 1 and 100 foot-candles, — so that deductions concerning the intermediate intensities, which are the significant ones, of 5, 10, 20 and 40 foot-candles are invalid. The criteria of comfort and work output are, according to the authors, unreliable. Thus they dispose of the considerable amount of data of previous investigators that indicate that for all practical purposes light intensities of 10 foot-candles are adequate.^{9, 26-29}

Sweeping conclusions based on the above experiments form the substance of most of the literature that during the last fifteen years has inundated engineering, psychologic, industrial, medical and popular journals recommending ever-increasing illuminations. At the same time, a considerable number of reports, less accessible to the public perhaps, but nonetheless authoritative, have led

to the conclusion that 10 foot-candles is sufficient illumination.³⁰⁻³⁵ It is pointed out in these latter reports that visual acuity increases rapidly from 1 to 5 foot-candles, slowly from 5 to 10 and only slightly above 10. Certainly intensities greater than 20 foot-candles have no practical significance.¹⁵

But from the medical point of view the unfortunate part of this higher illumination campaign lies not alone in the fact that it is unjustified on the grounds of efficiency. What is worse is the implication that the illumination in the average home and office results in some organic harm to the eyes, and thus the public is cajoled into increasing the lighting for presumptive health reasons. That inadequate illumination results in damage to the eyes is rarely stated directly, although the literature cited above is rife with threats of "permanent injury,"³¹ "tragic toll"³⁶ and "decply hidden penalties"³⁷ that "can only be revealed by careful and unique scientific research,"³⁸ and with such suggestive illustrations as a blind man being led by a Seeing-Eye dog.³⁹ The responsibility of the medical profession is here obvious, but it is difficult for the average physician, who has neither the time nor the interest to review the literature, to keep his equanimity in the face of the abundant propaganda. There is no generally acceptable evidence that poor illumination results in organic harm to the eyes any more than that indistinct sounds damage the ears or faint smells damage the nose. To be sure, prolonged concentrations under inadequate seeing conditions, estimated at less than 3 foot-candles,³⁶ will result in fatigue. But the fatigue is one of attention, and the complaint is generally a headache. There is no evidence that this results in cataract, glaucoma, separated retina or any of the other organic diseases of the eyes. For years it has been suggested that the so-called "unhygienic" condition of poor illumination and much close work result in nearsightedness. Luckiesh accepts this unqualifiedly, and in presenting it to the public, proposes another etiologic agent: reading from glossy paper.¹⁹ There is no satisfactory evidence for the theory that nearsightedness is the result of much close work, poor illumination or reading print on glossy paper, whereas there is much evidence against it.⁴⁰ There is no proof that what is generally called "poor illumination" results in organic disease of the eyes.

It has been asserted that "the new science of lighting becomes a humanitarian movement which should engulf every human being,"⁴¹ but for those who have not taken their lighting seriously and who in consequence do not have one of the light meters, which Luckiesh augurs will be part of every well-equipped home,⁴² the following information may be of interest. A new 40-watt frosted

bulb will provide an illumination of 10 foot-candles at 23 inches, 15 at 19 inches, and 25 at 14 inches.⁴³ Although this seems adequate for normal purposes, a somewhat more intense illumination may be desirable in certain conditions such as in uncorrected presbyopia, in which the smaller pupil, induced by the brighter light, makes up in part for the lack of visual acuity from insufficient accommodation.⁴⁴ This, of course, is not necessary when suitable glasses are worn. But the important thing is not that light requirements vary in different people, which in itself might be held as sufficient evidence to invalidate a universal mechanical meter,⁴⁵ but that when a person, as a presbyope, is benefited by more illumination he instinctively turns on more light. And he does this without any knowledge of what is happening to his heart rate, pupil and so forth. Contrary to the contentions of Luckiesh and Moss, there is no valid reason for believing that man cannot judge the amount of illumination that gives him easy and comfortable seeing. There seems little justification for the analogy that just as man needs a thermometer for measuring temperature or a pair of scales for weighing a beefsteak,⁴⁶ he needs a mechanical device to tell him how easily he reads. Anyone who has had the limited experience of getting used to a hot bath knows how much more variable the sense of warmth is than a thermometer indicates. Similarly, it is the person, with all the variables that make up a human being, who is going to do the reading, not the meter.⁴⁶

EYESTRAIN

Most patients and some physicians believe eyestrain to be a well-defined entity, having specific causes, manifesting characteristic signs and symptoms, being readily detectable by objective examination, and leading to permanent damage of the eyes if untreated. To the ophthalmologist, on the other hand, eyestrain, although a convenient term, has less positive implications. "To the patient it has a definite and satisfying meaning, but to the doctor who employs it, it is almost if not quite meaningless, so that by its use he [the ophthalmologist] does not really commit himself in any way."⁴⁷ Here an attempt will be made to describe this ill-defined syndrome, to discuss some of its causes, and to suggest its physiologic background in the light of modern ophthalmologic thought. There is little doubt that the description to be given accords with the majority of ophthalmologic opinion, but the responsibility for the interpretation of the symptoms must, in view of the scarcity of literature on the subject, rest with me.

The chief symptoms and signs that make up

the syndrome of eyestrain are headache, sandy feeling and aching of the eyes, pulling sensation in and about the orbit, unusual sleepiness, and hyperemia of the globe and lids. None of these or of the many other symptoms that might be included in the syndrome are specific.

The alleged causes of eyestrain are legion, but refractive errors, muscle imbalances and faulty illumination have received most attention. Any visual task requiring concentration, especially when some extraneous influence makes this difficult, is potentially a source of eyestrain. It is not so much the refractive error or other handicap to vision that is responsible for the symptoms of eyestrain as it is the effort that is made to overcome the handicap. Whether or not glasses are indicated cannot be determined by knowledge of the refractive error and visual acuity alone. The effort that the patient exerts to overcome what handicap he may have must be taken into consideration. This is a very practical matter, and it is failure to take cognizance of it that has led to much unnecessary giving and changing of glasses, especially by nonprofessional refractionists. Persons with small refractive errors, especially low grade hyperopia and astigmatism, have severe symptoms of eyestrain, whereas those with errors so large that presumably no voluntary effort is made to correct them have no eyestrain. Indeed, the latter may have eyestrain only after wearing glasses for the first time. By the same token, persons with normal ocular mechanisms may on occasion have typical and genuine strain on using their eyes. The symptoms of eyestrain, thought to be due to errors of refraction but also occasionally present with no such error, are thus attributable not so much to the peripheral origin as to a central mechanism that attempts to correct for the defect. It is possible that this central mechanism may be invoked and may produce typical symptoms of strain without any change in the eyes themselves, thus attesting to the purely central origin of the discomfort. This is seen, for example, when an out-of-focus picture is projected on the screen. Here there is no question of accommodation, muscular imbalances and so forth, which does not apply to an in-focus picture, but it is distinctly less comfortable to view.

Although the evidence for the central origin of eyestrain from refractive errors would probably be accepted by most experienced refractionists, the symptoms arising from muscle imbalances or from exertion of the extraocular muscles are generally thought to arise in the muscles themselves. Certainly the discomfort feels as though it came from the region of the orbit. Further

more, fatigue of striated muscles elsewhere in the body is commonly believed to be due to accumulation of metabolic waste products and consequent stimulation of the nociceptors in the muscles. A number of observations, however, are apparently irreconcilable with this idea of the peripheral origin of discomfort in the eye muscles. A few may be cited. If a person maintains upward gaze for any length of time he feels a discomfort about the eyes that may culminate in a headache. But a person who, owing to a supranuclear lesion, cannot look up has the same symptoms merely from the continuous attempt to look upward. Here there is no muscle contraction or accumulation of metabolic waste products in the muscle tissue. Another striking example is afforded by nystagmus, in which condition the eyes are continually moved back and forth for hours without fatigue, whereas similar voluntary movements by a person with normal ocular motor mechanisms would be extremely fatiguing. There is thus a good argument for the hypothesis that eyestrain from muscular exertion is, like that from refractive errors, of central rather than peripheral origin.

The nature of the central process that I have called "visual effort" is far from clear, but it is known that such a process occurs and that it is not motivated solely by the eyes. The alpha rhythm from the occipital cortex, as detected with the electroencephalogram, may be abolished merely by the attempt to see in the dark just as it is in response to a peripheral visual stimulus.⁴⁸ An interesting case has also been recently reported in which a bruit over an occipital hemangioma was exaggerated by the attempt to see.⁴⁹ Both these observations are qualitative indications of some of the central processes taking place with visual effort. It is in such terms that eyestrain may eventually be explained.

What has been said of eyestrain from refractive errors and muscle disturbances probably applies to strain from other causes as well. It is an effort syndrome arising from the performance of a visual task, usually in the presence of some handicap, and it makes little difference whether the handicap is one of refractive error, glaring lights, distracting noises or difficult texts. Eyestrain is a central process related to concentration. The presence of some extraneous factor rendering the visual task difficult might be appropriately called mental glare, inasmuch as it consists in something other than the visual task imposing itself on consciousness. Instead of being a simple entity, eyestrain is thus a complex process extending well into the psychologic realm, and is certainly not amenable to evaluation merely by objective examination.

Granted the validity of this concept, it is apparent that although eyestrain may cause various psychologic disturbances,⁵⁰ it does not result in any organic disease of the eyes. Nor would one expect that organic ocular disease from whatever cause would be made worse by eyestrain any more than by other psychic annoyances. It is also apparent that the treatment of eyestrain is symptomatic only. Glasses are analogous to crutches, and important as their service is in this capacity, they have no further therapeutic value so far as the eyes are concerned. The common allegation that "wrong glasses" have ruined one's eyes is entirely without foundation. This concept of eyestrain also suggests the error in ascribing a medical implication to many of the maxims that have arisen from purely intuitive considerations. The reason that one should write with the light over one's left shoulder is that this arrangement makes the shadows least bothersome. The opposite holds for left-handed persons. As for reading, it makes no difference over which shoulder the light comes. Nor does any harm, other than perhaps discomfort, come from reading in bed. The same applies to reading on the train. Many of the misconceptions that have arisen as presumed health or sight precautions are clarified by an understanding of the psychologic nature of eyestrain.

* * *

Much pseudoscientific evidence pertaining to illumination and eyestrain has been generally accepted and enshrouded with medical implications. Unfortunately, the medical profession has concerned itself little with the problems arising from these beliefs. There is, for instance, little or no discussion of them in ophthalmic or medical texts. It is hoped, therefore, that this review will bring to the attention of those who are the final arbiters of public health a reasonable and critical judgment in these matters.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27111

PRESENTATION OF CASE

First Admission. A sixty-one-year-old physician entered the hospital for study.

The patient was well until ten years previously, when he contracted lobar pneumonia; shortly afterward he developed a phlebitis in his right leg following a fall. During the next ten years he had six more attacks of phlebitis, four in the right leg and two in the left. At the end of this period he entered this hospital complaining of gas in his stomach occurring in the midafternoon and associated with nausea and belching, without vomiting. He had had these symptoms for two months and also complained of swelling and cramps in his legs, which he attributed to the old phlebitis. On examination at this time, the fundi showed slight nicking and tortuosity of the vessels, but the peripheral arteries were not palpable. The thyroid gland was slightly enlarged and appeared to contain several nodules. Examination of the heart was negative except for a soft systolic murmur at the apex; the blood pressure was 150 systolic, 84 diastolic. Examination of the urine and blood was negative. An electrocardiographic recording showed a normal rate and rhythm. The QRS₃ complex was of slightly low amplitude, with very slight slurring of QRS₂ and QRS₃. T₁, T₂ and T₃ were upright, and the chest lead was normal. X-ray studies of the sinuses, skull and gall bladder were negative; a gastrointestinal series showed multiple diverticula of the sigmoid.

Second Admission (three years later). The patient carried on for the next two and a half years, at the end of which he presented his physician with an electrocardiogram taken in California two months previously following an attack of pain said to be typical of coronary thrombosis. This recording was distinctly abnormal and was interpreted as being more in keeping with a basal infarct, including partial auriculoventricular block, than with an acute cor pulmonale from pulmonary embolism. His physician found moderate pitting edema of both legs from chronic varicosities. There was a very slight aortic systolic murmur, but the heart seemed normal in size, sounds, rate and rhythm; the blood pressure was normal.

An electrocardiogram was now essentially normal, with slight inversion of Lead 3. Fluoroscopic examination showed a full-sized heart with normal aorta and clear lungs. Six months later, the patient returned to his physician merely for the purpose of a routine check-up; fluoroscopic examination showed a large shadow in the middle of the right lung. The temperature, heart, and electrocardiogram were normal. An x-ray film of the chest taken the next day showed the diaphragm to be normal in outline, position and excursion. The right lower and middle lobes and the base of the right upper lobe contained multiple sharply defined areas of consolidation. These areas were in contact with the pleural surfaces and moved normally with the lung. There were at least seven separate areas of density. The right lower and middle lobes were probably reduced in size, the lower more so than the middle. The septum between the lower and upper lobes was convex downward and posteriorly. The largest areas of consolidation were in the superior margin of the middle lobe and in the apex of the lower lobe. There was no evidence of fluid. The mediastinum was moderately displaced to the right. The apex of the heart was sharp and pointed, suggestive of a small, sharply defined area of consolidation in the adjacent lung. The left lung and upper portion of the right were otherwise clear. The aorta was normal. Three days after this examination, the patient had a flare-up of his phlebitis in the right leg and was admitted to the hospital.

The right saphenous and femoral veins were divided. An uneventful convalescence followed, but one month later the patient noticed that he was slightly dyspneic and complained of pain in the right mid-chest anteriorly. X-ray examination of the chest showed what the roentgenologist interpreted as fresh pulmonary infarcts. The right common iliac vein and the hypogastric vein and artery were sectioned. Following this procedure, the patient developed a rise in temperature, with signs of consolidation in the right middle chest, and Type 3 pneumococci were isolated from the sputum. He was given sulfapyridine with apparent improvement, but continued to run a swinging temperature up to 101°F., the pulse running between 90 and 100, the respirations around 30. Approximately one month after the operation a blood culture grew an unidentifiable pneumococcus. The additional and relevant physical findings at this time were as follows: The chest showed limitation of motion on the right side anteriorly and posteriorly, and there was dullness to percussion from the second to the sixth rib

on the right anteriorly. The breath sounds were slightly diminished throughout the right chest anteriorly. Posteriorly on the right there was dullness from the sixth spinous process to the ninth, where percussion elicited slight tenderness. Tactile fremitus was absent at the right base, and the breath sounds were diminished progressively from the sixth spinous process down, becoming absent below the ninth. Examination of the heart was unchanged. The extremities showed edema, with marked pigmentation over the anterior surface of the shins. Over the next ten days the chest signs improved so that at the time of discharge there was a definite increase in resonance both anteriorly and posteriorly on the right, with less suppression of breath sounds over the involved areas. A positive blood culture was not obtained again.

Third Admission (four months later). The patient returned to the hospital for a check-up and because of pain in the right lower leg and foot of one month's duration. The pain had started in the big toe, and gradually extended to include the lower leg. It was worse at night and during rest, and was relieved by walking. The patient was a little dyspneic on exertion. Examination of the chest showed limited expansion on the right, with dullness, diminished breath sounds and coarse wheezes on this side. The right toes and foot became red when in the dependent position and blanched promptly on elevation. There were varicosities around the ankle, with slight edema, and tenderness was present over the dorsum of the right foot and lower leg, with limitation in dorsiflexion at the ankle. Pulsation was good, and there were no obvious temperature differences. Examination of the urine and blood was negative; the sedimentation rate was normal. The nonprotein nitrogen of the blood serum was 22 mg. and the uric acid 5.1 mg. per 100 cc. An electrocardiogram was within normal limits. X-ray study of the chest showed that the large area of density in the right middle lung field had now completely disappeared, leaving only a few linear bands of density extending laterally and downward from the hilus. The diaphragm was irregular in outline and limited in excursion. The left lung was clear, and the heart shadow slightly displaced to the right. The heart showed slight prominence in the region of the left ventricle. There was no evidence of fluid or active disease. X-ray films of the legs were essentially negative. The patient was discharged three days later with a diagnosis of peripheral neuritis.

Fourth Admission (thirteen months later). Eight months before this admission, the patient had developed a cold that went to his trachea, with the

result that he had difficulty with wheezing respirations, and from time to time a little "asthmatic breathing." An x-ray film taken five months before entry showed a high right diaphragm, with numerous thin lines at the site of the large areas of consolidation described on previous examinations. There were no remaining areas of consolidation and no new lesions. Three weeks before admission the patient became short of breath on exertion, and, in addition, had attacks of nocturnal dyspnea during which he was compelled to sit upright, although, in general, lying flat gave no trouble. This dyspnea was accompanied by a tiring, brassy cough productive of a little white frothy sputum and a heavy feeling in the chest under the sternum. The onset of these symptoms was not sudden, nor was there pain.

On examination, the patient was cyanotic, with some increase in respiratory rate, and a slight respiratory crow was audible. Examination of the heart was negative except for slight displacement to the right; the blood pressure was 130 systolic, 82 diastolic. The right chest was retracted, and posteriorly at the base the percussion note was dull and the breath sounds, vocal and tactile fremitus absent. The liver was palpable two finger-breadths below the costal margin on deep inspiration. Examination of the urine and blood was negative; the red-cell count was 5,450,000, the sedimentation rate normal, and the vital capacity of the lungs 1741 cc. An electrocardiogram was within normal limits. X-ray examination of the chest showed the diaphragm to be obscured by a homogeneous density, which shifted when the position of the patient changed. There was consolidation at the apex of the right lower lobe and in the region of the anterior portion of the right middle lobe. The heart was to the right of the spine, without shift of the mediastinum. The right side of the diaphragm moved very little. The left lung was clear except for slightly diminished radiance at the base. X-ray study of the gastrointestinal tract showed the esophagus, stomach and duodenum to be essentially normal. The esophagus was deviated toward the left at the lower third. The right chest was tapped on two occasions, but only once was fluid obtained, and then but 3 cc. were withdrawn. This fluid contained 2250 red cells, 6600 lymphocytes, and 400 polymorphonuclears per cubic millimeter. No tumor cells were identified by the pathologist. The patient continued to crow and wheeze on respiration, the sounds being heard over the superior mediastinum and remaining audible in whatever position he assumed. Examination of the trachea and vocal cords was negative. The patient was discharged on the ninth hospital day.

Final Admission (three weeks later). In the interval, the dyspnea, asthmatic breathing and cough with slight sputum had persisted, and had indeed become slightly more pronounced. Two weeks before admission the patient began to suffer from profuse sweating and periods of chilliness without fever. A blood examination was said to have shown malarial parasites, and he was given a course of atabrin (15 tablets). This was followed by a diminution in size of the "right lobe of the liver," but did not change the clinical course. Eight days before admission, he developed in the lower chest a sudden pain, which was not associated with an increase in dyspnea. This pain lasted four days and was relieved promptly by manipulation of the vertebrae. However, at this time he complained of a sudden right epigastric pain associated with nausea and relieved by "Ludozan." Subsequently any solid food initiated this pain, which was accompanied by extreme localized tenderness. On one occasion, two days before admission, the patient raised a small amount of blood-streaked sputum. With the increase in dyspnea there was some orthopnea, and the pulse became intermittent at 90; the blood pressure was 110 systolic, 70 diastolic. The patient was given 0.5 cc. of digalen, which lessened the right-upper-quadrant abdominal tenderness and cleared the rales heard in the chest. The pulse became regular at 84.

On examination the patient showed striking evidence of weight loss. He was dyspneic, with a rasping, asthmatic wheezing precipitated by any movement. He coughed frequently, producing a thick mucopurulent sputum. There was slight cyanosis, but no obvious venous engorgement of the neck veins. The trachea was displaced to the right. The right chest was flat with limited expansion, and there was dullness to percussion from the third interspace down, with diminished breath sounds. Posteriorly on the right there was a dull to flat percussion note from the lower scapular region down, with absent breath sounds and tactile fremitus. Slight hyper-resonance was present at the right base. The heart was displaced to the right, and a rough systolic murmur was heard along the left sternal border. The pulmonary second sound was slightly greater than the aortic second, the rhythm was regular, the blood pressure 122 systolic, 65 diastolic. Examination of the abdomen revealed tenderness 5 cm. below the xiphoid and slightly to the right. The liver margin was palpable 4 cm. below the costal margin in the mid-clavicular line and was diffusely tender. Peripheral edema was absent; the right leg was somewhat larger than the left, but was not tender.

No pulsation could be felt in the right dorsalis pedis artery, but it was present on the left.

The temperature was normal, the pulse 98, and the respirations 35.

Examination of the urine showed a + test for albumin. Examination of the blood showed a red-cell count of 4,410,000 with a hemoglobin of 15.1 gm. (photoelectric-cell technic), and a white-cell count of 9500. The nonprotein nitrogen of the blood serum was 19 mg., the serum protein 6.1 gm., the calcium 11.1 gm., the phosphorus 3.9 mg. per 100 cc., and the chlorides were 97.8 milliequiv. per liter. The sedimentation rate was normal. Examination of the stools showed a + guaiac test.

X-ray films of the chest showed very little, if any, change in appearance since the last observation. There was definite evidence of fluid and an extensive destructive process in the right lung. The left lung appeared normal.

On x-ray study of the abdomen, the outline of the diaphragm was not visible on the right side, and there was dullness extending a little below the twelfth rib. The kidney on this side was easily seen, appeared normal in size and shape and was apparently displaced downward so that its lower pole overlay the crest of the ilium. The shadow above it was of homogeneous density and was possibly due to an enlarged liver. There was no abnormal shadow on the left side. There was a moderate amount of gas in the colon and small bowel. The spine showed hypertrophic changes.

An electrocardiographic recording showed a normal rhythm with a rate of 100. T₁ was low and slightly diphasic. S-T₂ was sagging with slight late inversion. T₃ was inverted, R₁ upright and T₄ inverted (for the most part, late).

The patient never improved, continued to complain of severe attacks of epigastric pain and was weak, slightly cyanotic and dyspneic, with a troublesome cough. Four days after admission he again raised rusty sputum and continued to do so thereafter; the white-cell count was 15,800. He was placed in an oxygen tent, given diuretics and heparin. On the thirteenth hospital day the patient passed a tarry stool, and for ten days thereafter the stools were guaiac positive. The temperature was now 101°F. At this time the right elbow became painful on any motion and the left forearm and hand slightly swollen; edema of the feet developed, more marked on the left, with tenderness in the inner right mid-calf. Latterly the patient became disorientated, peripheral edema increased, the liver grew larger and tenderer, and the temperature rose to 102°F. Death occurred on the thirty-seventh hospital day.

DIFFERENTIAL DIAGNOSIS

DR. WILLIAM B. BREED: Ten years before the final admission this patient came in complaining of gas in the stomach with nausea and belching, but no vomiting. The x-ray films showed merely diverticula of the colon. The electrocardiogram showed nothing specific, merely slurring of the QRS₂ and QRS₃. The patient was then apparently discharged from the hospital with no diagnosis. Certainly no one found out why he was having indigestion.

Three years later, at the age of sixty-four, he returned to the hospital with the story that he had had pain in the chest, and produced electrocardiograms that had been interpreted by somebody as representing basal infarction with partial auriculo-ventricular block. The heart at this admission, however, was entirely normal, and another electrocardiogram showed only slight inversion of T₃, which means nothing. I should like to know who interpreted the other electrocardiogram and whether or not we can safely say that the patient had had a basal infarction of his heart. I am inclined to doubt it. He had a flare-up of phlebitis during this admission and was operated on, the right saphenous and femoral veins being sectioned. Obvious pulmonary infarction was found by x-ray examination. Then the common left iliac vein and artery were sectioned. This was followed by signs of consolidation in the right chest, the sputum containing Type 3 pneumococci. At that time an unidentified pneumococcus was recovered from the blood; then the chest cleared, I assume, and the patient went home.

About four months later he had pain in the right lower leg and foot for one month; it was worse when resting and relieved while walking. There were varicosities about the ankle. An electrocardiogram was reported at that time as normal, and the blood chemical findings were perfectly good. The patient had no renal difficulty. The x-ray studies at that admission should be of interest. He was discharged then with the diagnosis of peripheral neuritis, which I am inclined to doubt. Thirteen months later, he returned to the hospital with the story that eight months previously he had had a cold, which had gone to his trachea, and that he had been having asthmatic breathing on and off ever since that time. Additional x-ray films showed numerous lines at the site of the mass, which had disappeared. Three weeks previously, the patient had had attacks of nocturnal dyspnea associated with brassy cough and a heavy feeling under the sternum, but no pain. At this time he was cyanotic, and the heart was displaced to the right.

At the fourth admission, the chest was tapped, and 3 cm. of fluid was withdrawn, which showed 2250 red cells and 6600 leukocytes with 400 polymorphonuclears, and which certainly was not just blood and must indicate either inflammation or some malignant process. No tumor cells were identified by the pathologist. I think it would be of value to try to get some order out of this chaos by taking up the various systems, discussing first the one that is least likely to cause this trouble. That, I believe, is the metabolism, as reflected in the chemical examinations. The phosphorus is all right, the nonprotein nitrogen is normal; the calcium is 11.1 mg. per 100 cc., which is very slightly above the high normal of 10.8. With that single finding I cannot go any farther, but I do not see that it is of any significance.

I think the next group of symptoms or signs I should like to take up would be those pertaining to the cardiovascular system. It seems to me very unlikely that this man had had a basal infarction and then had a return of the electrocardiogram and other findings to normal. My experience is that younger people with infarction have a return to a normal electrocardiogram more frequently than people over sixty. It is not often that the signs of infarction disappear in a man of this age. Therefore, I am doubtful about this coronary occlusion. The cardiac situation does not seem to me to be very prominent. The patient had a fall in blood pressure, and toward the end probably did have congestive failure, but I do not believe that he suffered any accident to his coronary arteries.

The pulmonary situation in the first part of the illness is quite simple. The patient had phlebitis and recurring pulmonary infarction, which we know about; and up to the latter part of the illness the pulmonary situation seems quite clear. The x-ray films showed definite clearing of the initial lesions. Then latterly he developed again a definite pathologic process in the right chest, which caused pulling of the heart to the right, indicating a collapse of the middle lobe and perhaps the right lower lobe. I believe that this was some destructive process in the right lung and was the main cause of his death.

I should like to have Dr. Hampton interpret the x-ray films.

DR. AUBREY O. HAMPTON: I looked over these films carefully. The patient had many examinations and many films. These are the most interesting. If you want to know anything about the others, I have them here. At the first examination there were multiple, sharply defined areas of consolidation in the right middle and lower

lobes. They corresponded to the margins of these lobes and had the general shape and appearance of infarcts. There was no pleural reaction, however. Here on the left side is a short linear shadow continuous with a v-shaped configuration of the apex of the heart, which we thought was a healed infarct and which, perhaps, was related to the cardiac episode. The patient might have had precordial pain and cardiac embarrassment with it. One month later this picture in the chest had not changed. Another film taken twenty-three days later, following the first operation, showed obliteration of the previously clear costophrenic angles. If one compares the lateral views, the shadow of the heart is covered by new sharply defined masses, so that we may assume that there were two more infarcts following the first operation. At that time the patient said, "I have finally had the pain you have been trying to get me to admit." Nearly two and a half months later, following the second operation, this film—one of the many films at this time—showed pleural effusion and reduction in size of the masses in the right lung. Four months after that all the lesions in the lung had practically disappeared, leaving numerous lines similar to the one noted at the left border of the heart, so that we then assumed that the infarcts had healed.

DR. BREED: So far we are even.

DR. HAMPTON: These are the films of the last admission. There is now a change in the whole picture. The patient came in with about the same evidence of pleural disease that he had following the second operation. There are also masses in the right mid-lung field, and in addition a circular area of diminished density, which looks like a cavity. The trachea, heart and mediastinum have all shifted a little farther to the right. We examined the esophagus and trachea, trying to discover the cause of the discomfort and wheezing, but could find very little wrong, only a little esophageal displacement where it crossed the aorta. The stomach was normal, and the shadow of what we thought was his liver was large. The kidney was displaced downward. The spleen was not enlarged so far as we could tell. This final film was taken one month later, and shows numerous, irregular cavities in the region of the middle and lower lobes. Of course the heart would shift to the right if the lung were destroyed.

DR. BREED: I think it is reasonably clear that this patient had a serious chronic condition in the right lung. Whether it was due to primary cancer in the bronchus or to a primary destructive lesion farther down, or whether it was metastatic cancer or multiple abscesses in the collapsed

lung, I am sure I have not yet a clear idea, but I am reasonably certain that this man died of pulmonary disease primarily. We then come to the question of tarry stools, and this very peculiar complaint of tenderness and pain in the same spot when he swallowed food. Is that a good description of what he really showed? You will admit that it is a peculiar symptom.

DR. TRACY B. MALLORY: Can you answer that, Dr. Stetson?

DR. RICHARD P. STETSON: After eating, the patient had spontaneous pain, which he localized in the right epigastrium, and there was a spot of persistent tenderness just to the right of the mid-line.

DR. BREED: Let us consider the gastrointestinal tract. When he first came in, the complaint was indigestion, and nothing more is said about the tract throughout the whole long illness up to the point of this situation toward the end. It seems a far cry but it is possible, I suppose, that he had some cancer in his gall bladder, with metastases to the lung, and possibly later erosion of the esophagus or some other portion of the gastrointestinal tract, with the production of tarry stools. I cannot believe that he died suddenly from hemorrhage, although he did have this large tarry stool. Though the intestinal tract may have been secondarily involved, I do not believe it was a primary feature of the disease. I think that the patient died of cancer primarily in his chest, which may have been complicated by multiple abscesses behind an obstructed bronchus. Although he probably had some terminal heart failure, I doubt if this man had an occlusion of an artery in his heart.

DR. MALLORY: I should be glad to have you cross-examine any of the expert witnesses. They are nearly all present—Dr. White, Dr. Faxon, and Dr. Stetson.

DR. BREED: Dr. White, you are first. You were satisfied that this patient had had a basal infarct?

DR. PAUL D. WHITE: I was the first of the chain, and then was less in touch with him as the heart began to fade from the picture. I saw him first in May, 1938. He had come back from California with the story and electrocardiogram typical of something happening suddenly in the chest. The electrocardiogram showed auriculoventricular block and deformity of Q and T (prominent Q's and inverted T's) in the second and third leads. The auriculoventricular block seemed to indicate not an acute cor pulmonale but basal myocardial infarction in all probability. We had never encountered heart block before in acute dilatation secondary to pulmonary embolism. My first diag-

nosis was therefore coronary thrombosis in May, 1938, and phlebitis of twelve years' duration. I checked up six months later, when he felt perfectly well, but I was amazed at that time to find a large shadow in the right lung. I sent him then to Dr. Hampton. You have heard the rest of the story from him.

DR. BREED: Were you surprised to see the heart and electrocardiogram return to normal?

DR. WHITE: No, that happens occasionally with basal myocardial infarction, so that despite the fact that the electrocardiogram was normal in May and again in December, I did not change my original diagnosis but added that of pulmonary infarction.

DR. DONALD S. KING: Could it all be the result of septic infarction in that area?

DR. BREED: With multiple abscesses? I suppose it could. I do not know how one can explain the tarry stool and positive guaiac tests on that basis.

To go back to the heart: The last electrocardiogram was perfectly consistent with digitalis effect or with, perhaps, some coronary disease, but I cannot interpret it as coronary occlusion. Of course, the patient may have had one after the last electrocardiogram, but there is nothing in the history to indicate it.

DR. WHITE: I think your reasoning is excellent.

DR. BREED: It may be excellent, but I do not think it is going to produce anything brilliant here. I have committed myself to cancer, either primary or secondary in the right chest. I should be inclined to think it was primary and not secondary.

DR. GEORGE W. HOLMES: One of the things that has bothered Dr. Breed is this intestinal hemorrhage. I should like to suggest the possibility of embolus to the mesenteric arteries.

DR. BREED: I did consider it, but there was nothing in the story to indicate its presence. The patient lived for ten days after the positive guaiac, and nothing was said about an acute abdominal situation. I hate to surrender the explanation of this tarry stool but I have not a thought, except erosion of the gastrointestinal tract by cancer.

DR. KING: If you saw the last x-ray films and did not know the story, what diagnosis should you make, Dr. Hampton?

DR. HAMPTON: I should have to say primary carcinoma of the lung with metastases to the liver.

DR. KING: If you saw the x-ray films alone, you could not escape that diagnosis, but I do not know whether it is a good one.

DR. BREED: I am willing to make that diag-

nosis, but I am not going to say metastasis to the liver.

DR. HAMPTON: How are you going to account for the large shadow in the right upper abdomen?

DR. BREED: By his congestive failure.

DR. HAMPTON: His spleen is not enlarged.

DR. BREED: Well, what of it?

DR. HAMPTON: That is a very big liver, if it is the liver. I am not sure that it is.

DR. BREED: If you do not know, I should not be expected to, and these men will not tell me; I therefore do not think they knew either.

CLINICAL DIAGNOSES

Pulmonary infarction.

Bronchopneumonia.

DR. BREED'S DIAGNOSES

Cancer of the lung, ? type.

Erosion of gastrointestinal tract, ? site.

Phlebitis.

Pulmonary infarction (old).

ANATOMIC DIAGNOSES

Reticulum-cell sarcoma involving right lung, pleura, stomach, retroperitoneal tissues, mediastinum and trachea.

Thrombosis of inferior vena cava, common iliac, femoral and deep veins of legs, bilateral.

Arteriosclerosis, slight, aortic and coronary.

Cholelithiasis and choledocholithiasis.

Stricture of left ureter.

Hydronephrosis.

PATHOLOGICAL DISCUSSION

DR. MALLORY: To start with the negative findings: The heart was small, the coronary arteries capacious, and there was no significant amount of coronary sclerosis. On the positive side, this man was riddled with tumor. The largest amounts of tumor were in the right thoracic cavity, partly in the form of massive pleural involvement but also as a complete neoplastic replacement of the right lower and middle lobes. In the midst of the tumor were many small cystic cavities where the tumor had broken down. The liver was normal in size, small,—weighing 1500 gm.,—and the mass that had been felt and interpreted on x-ray examination as liver was an immense mass of tumor in the gastrocolic ligament, which ran backward and was continuous with more tumor, chiefly centering in the nodes around the head of the pancreas and also destroying the pancreas itself. A peculiar finding was that all the mesenteric tabs in the sigmoid were infiltrated with

neoplasm. A significant amount in the posterior mediastinum had invaded through the trachea at one point, and a small tumor mass was present within the trachea. I therefore think that the wheezing and the asthmatic breathing were due both to intrinsic and to extrinsic narrowing of the air passages.

The probable source of the tarry stool was the stomach, which presented a most extraordinary appearance of about 50 separate small tumors in the mucosa, most of them with shallow ulcerations. The widespread distribution of the tumor masses and the lack of obvious primary focus suggested some form of lymphoma, and on microscopic examination we finally classified this as a reticulum-cell sarcoma. We were able to find in the left lung one linear scar, which Dr. Hampton pointed out on first entry and which I think represented a healed infarct. All evidence of the multiple infarcts that Dr. Hampton had described in the right lower lobe was entirely obliterated by the neoplastic growth. Despite the various venous ligations that this man had had, he still had a source for pulmonary emboli, since the thrombotic process extended well up into the vena cava. Incidental findings, which probably played no role in his symptomatology, were a stone in the common duct and a stricture of the left ureter, with a secondary hydronephrosis.

Dr. HENRY H. FAXON: The operation was done at another hospital, and was attended, I am told, with a certain amount of difficulty. I believe that bleeding was encountered and prompted the surgeon to ligate the artery as well as the vein. The only other reason that could be advanced for sectioning the artery would be its alleged beneficial vasomotor effect on the deep phlebitis. Dr. John Homans, I believe, considers that in such cases section of an artery will be helpful, but I should be opposed to carrying out this procedure. I believe that lumbar sympathectomy or injection would be more satisfactory if the purpose were to secure distal vasodilation.

Dr. WHITE: May I add one word about the electrocardiogram? During the last few years, I have occasionally found it difficult to tell the difference by electrocardiography between basal myocardial infarction and acute dilatation of the heart secondary to pulmonary embolism. As it turned out, there must have been that confusion here even to the point of believing that this patient had transient heart block with pulmonary embolism. Why that happened, I do not know, unless asphyxia could have been responsible, as has been proved in animal experiments. The terminal

electrocardiographic changes could be explained by the serious final illness.

CASE 27112

PRESENTATION OF CASE

A twenty-year-old girl entered the hospital complaining of pain and swelling in the right ankle.

The patient stated that seven months before admission, while she was walking, a sudden pain developed in her right ankle and was severe enough to initiate slight nausea. This was followed by swelling, fever and an area of redness on the outer surface of the ankle. These symptoms lasted for two weeks, then subsided, but three weeks later a similar episode occurred, apparently quite spontaneously. During the months before admission, the patient suffered six such attacks, and each time the symptoms gradually subsided, except for the persistence of slight swelling. Between times there was no pain, no inconvenience, but occasionally a slight twinge occurred in the ankle when she stepped in a certain way. Four days before admission, she happened to brush her ankle against a chair and there was pain, followed in several hours by swelling and tenderness. The pain increased, disturbing sleep, although somewhat relieved by elevating the part. She had not lost weight.

On examination the patient was well developed and well nourished and in no apparent distress. Examination of the heart, lungs and abdomen was negative; the blood pressure was 120 systolic, 80 diastolic. Over the right external malleolus there was a localized area of nonfluctuant swelling and redness, with a slight increase in surface temperature. Tenderness was present maximally at the lower end of the malleolus below the point where swelling was most marked. Active and passive movements of the joint were not painful or limited. No other joints were involved, and the regional lymph nodes were not swollen or tender.

The temperature, pulse and respirations were normal.

Examination of the urine showed a + test for albumin. Examination of the blood showed a red-cell count of 4,520,000 with a hemoglobin of 75 per cent, and a white-cell count of 12,100 with a normal differential. The sedimentation rate was normal. The serum calcium was 10.9 mg., the phosphorus 3.5 mg. and the protein 6.7 gm. per 100 cc., with the phosphatase 2.9 units. A blood Hinton test was negative, and agglutination reactions for *Eberthella typhosa*, *Salmonella paratyphi*, *S. schottmülleri* and *Brucella abortus* were negative.

Tuberculin tests were negative in dilutions of 1:10,000, 1:1000 and 1:100.

X-ray films of the right ankle showed that the distal 2.5 cm. of the right fibula was deformed into a multilocular cavity with coarse irregular trabeculation. The external malleolus was not involved, but the cavity probably reached the joint surface medially. The borders of the cavity were rather ill defined, and there was a fracture through its posterolateral wall, with periosteal new-bone formation in this area. A fairly marked diffuse soft-tissue swelling was present on the outer aspect of the leg.

X-ray studies of the chest, skull, bones of the forearms, wrists, humeri, lumbar spine and pelvis were negative.

On the seventh hospital day a biopsy was performed.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE: We have an apparently otherwise healthy young girl with a lesion in the lower end of the fibula, which has produced symptoms for seven months, and I believe that the first question we must try to decide is whether or not this can be an inflammatory lesion. There is nothing in the history to suggest a previous infection. The temperature, pulse and respirations are reported as normal. The patient had a slightly elevated white-cell count with a normal differential. A story of this duration with intermittent symptoms, chiefly pain, not only with activity but also with rest, is fairly unusual for infection. In addition, agglutination tests for one thing and another were negative. Although I believe it is possible, I think it is unlikely that she had infection. One other point in regard to infection: the initial onset of trouble was pain while walking. In view of the subsequent demonstration of a fracture line in the x-ray films, it seems possible that the initial symptom might have been the result of a pathologic fracture, which would be extremely unusual for the first symptom of osteomyelitis. Just in passing, I might say that it is extremely unlikely that this is either syphilis or tuberculosis.

We always have to consider parathyroid disease in any bone lesion. The calcium, phosphorus and phosphatase do not suggest parathyroid disease. It is certainly not simple cyst from the x-ray appearance, and the position in the bone is unusual, because simple cysts occur more toward the center of the shaft.

Benign tumor might be considered next. Giant-cell tumor can be ruled out because of the x-ray appearance and the fact that giant-cell tumor is

usually confined to the epiphysis. This might conceivably be a chondroma, or, more likely, even an angioma of some sort.

This motheaten appearance suggests multiple myeloma, which with this duration should give involvement of bone somewhere else, and, again, the patient after this length of time probably would not be healthy in appearance. It could conceivably be lymphoma or something in the lymphoma series; reticulum-cell sarcoma is the likeliest possibility. Metastatic disease would have to be considered. It is not the usual appearance of the bone destruction that we see in metastatic disease. There is some new-bone formation here. Whether that is due to the old fracture or not is difficult to say. Osteogenic sarcoma is certainly a possibility. There is no great elevation of the periosteum, as we usually see in osteogenic sarcoma, and no ray formation, but osteogenic sarcoma frequently occurs without that.

Perhaps Dr. Holmes will help us at this point.

DR. GEORGE W. HOLMES: I think I know the diagnosis in this case. I have seen it before. Of course, in the lower end of the fibula there is an obvious lesion, which is almost wholly destructive and which occupies a considerable portion of the bone, but it does not look like an inflammatory lesion.

Then we come to tumor — whether it is benign or malignant. It is apparently a rather vascular tumor, and the only benign tumor that could possibly resemble it is an angioma, which, of course, is rare. The chances are in favor of primary malignant tumor.

DR. WALLACE: Should you say that there is a fracture through the lower end of the fibula, with new-bone formation at this site associated with it?

DR. HOLMES: It is not very obvious, but I think that there is one. If there is a fracture there, that makes it more difficult to interpret the significance of any periosteal proliferation.

DR. GRANTLEY W. TAYLOR: What are the characteristics that justify your saying that it is a highly vascular tumor? What are the x-ray characteristics?

DR. HOLMES: There is a good deal of bone absorption without bone proliferation. I have no very good grounds for my statement when you pin me down, but a vascular tumor shows a lot of bone destruction without much proliferation as a rule. There are trabeculae, moreover, throughout this tumor, whereas if it were a fibroma, or a fibrosarcoma one would expect destruction of all the bone. This apparently spreads irregularly

through the bone, leaving trabeculations, a thing that the vascular tumors are likely to do.

DR. WALLACE: Should you say that the periosteum is elevated to any great extent?

DR. HOLMES: There is some elevation.

DR. WALLACE: It comes down to the question of whether or not this is osteogenic sarcoma. The local signs are in keeping with that diagnosis—the redness and increased heat locally. The pic-

any given reading. One other point about Ewing's tumors is that they are less likely to have new-bone formation. The onion-skin appearance in the region of the periosteum that we frequently see in Ewing's sarcoma is not present here. However, we have seen this appearance in osteogenic sarcoma and the ray formation commonly associated with osteogenic sarcoma in Ewing's tumor. I believe, with all the evidence at hand, that a final conclusion could be reached only by biopsy, but I shall say that I consider the likeliest diagnosis to be Ewing's tumor.

DR. CHANNING C. SIMMONS: Like Dr. Holmes, I do not know that I am qualified to discuss this case, for I saw it clinically. I made the correct diagnosis, not on the evidence submitted, but because I had seen a similar case some time before. In all cases of bone disease, one has to consider four general possibilities: generalized bone disease, metastatic tumor, an inflammatory condition and primary bone tumor, either benign or malignant. In this case, with the data we have, metastatic tumor and generalized bone disease may be ruled out, which brings us down to an inflammatory condition or tumor. The patient had pain and evidence of tumor in the area for some time, with redness. I do not know whether or not she ever had a temperature, but she had none on admission to the hospital. On examination, however, she had a slightly elevated white-cell count, which might be due either to inflammation or to bone tumor, for a malignant tumor occasionally gives an elevated temperature and white-cell count. From the story she obviously had had trouble with the ankle for some time, followed by an acute attack of pain probably owing to the crack and tear through the periosteum. Of the inflammatory conditions we have to consider syphilis, tuberculosis and osteomyelitis. The blood Hinton test was negative. I do not think it is tuberculosis, for the x-ray film does not look like it. Osteomyelitis is a definite possibility. The benign bone tumors, with very few exceptions, cause no pain. The exception is giant-cell tumor and sometimes a central osteoma. I have never seen a central osteoma, but they are said to be painful. This patient had a bone-destructive lesion, demonstrable by x-ray, and a normal temperature. I believe that it undoubtedly is a malignant tumor of some form, either osteogenic sarcoma or Ewing's sarcoma. In giant-cell tumor with bone destruction, the destruction is usually very sharply marked at the top, with a sharp angle at the periosteum, and extends to the joint cartilage. Ewing's sarcoma is rare in this situation. It usually is in the shaft, but can

FIGURE 1.

ture is a little confused by the fracture. One ordinarily would expect a little more new-bone formation with osteogenic sarcoma of seven months' duration.

A likely possibility is, I believe, a Ewing's sarcoma, which can and occasionally does occur in this position in bone. The story of intermittent pain and local signs is common in Ewing's tumor. Early fracture is not unusual in weight-bearing bones. The slightly elevated white-cell count, with the normal differential, is in keeping with Ewing's tumor. I might say that, so far as bone tumors are concerned, elevation of the phosphatase is associated with new-bone formation. Of course, the reading is normal in this case, but in osteogenic sarcoma the readings vary from time to time, so that it is not necessarily elevated at

occur in any situation. I believe that this is probably a Ewing's sarcoma, but think it is impossible to make a diagnosis without a biopsy.

CLINICAL DIAGNOSIS

Benign giant-cell tumor of fibula.

DR. WALLACE'S DIAGNOSIS

Ewing's tumor.

ANATOMIC DIAGNOSIS

Ewing's tumor.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: A biopsy was performed on this patient, and a diagnosis of Ewing's tumor made. There was then considerable discussion about the best mode of treatment. Dr. Taylor can tell us how the argument ran in the tumor clinic.

DR. TAYLOR: The discussion revolved about whether we were ever going to cure Ewing's tumor of the long bones by any means, and there was a great deal of pessimism expressed. Dr. Simmons has records in the registry of bone sarcomas of some cures by means of radical surgery. The response of the immediate local process to x-ray therapy is very gratifying in controlling the local manifestations of the disease until the patient succumbs to the pulmonary metastases. Control of the local process is all that can be secured by radi-

cal amputation, and the only hope in surgery is that one may obtain complete early removal of the disease and get rid of it before the pulmonary metastases have been established. It is perhaps reasonable to hope that effective local radiation might bring about the same result, namely eradication of the local process before dissemination has taken place. Whatever method of treatment is followed, the results have been uniformly very poor. I think that generally the radiologists believed that they would like to try radiation therapy on this case, and the surgeons thought that they would like to carry out amputation. A very poor third method of treatment was brought up only to be condemned, and that was the question of whether a resection of the involved bone could be carried out. I believe that the patient was finally treated by radiation.

DR. MALLORY: She is undergoing x-ray treatment now.

DR. SIMMONS: In the registry there are records of some patients who lived without disease over five years. Two of these cases that I know of were controlled with radiation treatment. The others were treated by amputation. Unfortunately, statistics based on the cases reported to the registry are misleading, because surgeons are likelier to report favorable than unfavorable cases. I personally looked up 35 consecutive cases of Ewing's sarcoma treated by radiation or surgery—in all of which the patients are now dead.

PHYSICIAN VERSUS PHARMACIST

OUR esteemed, if relatively youthful, contemporary, the *Journal of the American Medical Association*, has taken a recent fling—and a deserved one, we believe—at our present most popular panaceas, the total vitamins.* The vitamins have had an interestingly prolonged build-up. Their existence was recognized, even if their nature was unknown, when Captain Cook first sailed the south Pacific and when the Dutch fishermen of the sixteenth century fed cod-liver oil to their babies to prevent that same rickets that Glisson so carefully described in 1650. It was not until 1911

that Funk first used the word, spelling it with a final "c," but these were not vitamins plus.

Cod-liver oil in those better days before horsepower replaced the horse cured only rickets; the juice of limes and other citrus fruits was used merely for its direct attack on scurvy; vitamin B, majestic, undivided and alone, made dietary war on the scourge of beriberi, until the alphabet gave substance to the conquest of pellagra by conferring a new letter on its conqueror.

The picture has been changing with increasing rapidity. Ultraviolet radiation has long since taken its stand as a practical counterpart of vitamin D; the vitamins no longer simply cure deficiency diseases but are essential contributors to positive health; vitamins E and K have been added to the list, and vitamin B has undergone lightning-like and repeated mitosis. The vitamin B complex, indeed, must now strut its part weighed in gammas, measured in international and Sherman-Bourquin units, and subdivided into numbered fractions—riboflavin and nicotinic acid, the filtrate factor, pantothenic acid, factor W, the factor of rat antidermatitis and the antigraying-hair factor.

A decade ago the vitamins constituted the coming therapeutic fact. Today, with a few endocrine hormones and the infant sulfa sisters sharing the stage, they are therapy itself.

The *Journal of the American Medical Association* tells us, in this same exposé of "vitamins plus," that more than two hundred vitamin products were pictured recently in an advertisement by a Chicago *department store*. No advertisement that we have yet seen informs us that all the necessary vitamins, in suitable quantities for those who are able to assimilate them, may be present in a well-balanced, properly prepared diet.

The vitamin preparations that can be sold over the counter and taken with presumable safety continue to capture the popular imagination, but it is also more than a half-truth that we who are medical practitioners have largely, and perhaps perforce, given over our therapy to the purveyors of proprietary preparations. Our investigative col-

*Editorial Nonplusing "vitamins plus" J. A. M. A. 115:1639, 1940

leagues, as we know, have been devising new methods in their laboratories and their clinics, but it is on the pharmaceutical houses and their detail men that we rely for the real ammunition of our practice, and to know where to buy and how to use the pills and potions, the panaceas and palliatives that scientific ingenuity and economic enterprise are supplying to us in such an endless stream.

We cannot master it all; we have little basis for selection; we know that it may take years to establish the real value of many of our vitamin preparations, our vaccines, our hormones and our drugs, and yet we cannot risk dropping out of the procession that so assuredly brands itself as medical progress.

Pharmacy is now far too complex for the corner pharmacist to supply the needs, much less the demands of the times, and the manufacturing pharmaceutical firm of good repute has become a very necessary adjunct to the effective service that we should all like to give. Is it, however, a part of this service that a single firm should list no fewer than twenty-four vitamin products running the gamut of the alphabet in various combinations from A to K, from alpha to omega and beyond?

POISON-IVY DERMATITIS

DERMATITIS from poison ivy—the shiny, three-leaved pest draped abundantly over New England scenery from spring to winter—is always with us. The vine was probably a hazard to the comfort of the Pilgrims and, like sunburn, hay fever and mosquito bites, flourishes as a disturber of the peace of both natives and summer visitors. The variations in the susceptibility of a person to the plant and the latent period between the exposure to its poison and the involvement of the skin are emphasized anew in this issue of the *Journal*.

The monograph, *Dermatitis Venenata*, published in 1887 by James Clarke White,¹ the first professor of dermatology at Harvard Medical School,—and in this country for that matter,—presented the results of keen observation, an ex-

cellent botanical knowledge and a wide clinical experience with the effects of this plant on the skin. McNair² developed much of importance regarding susceptibility to the plant and the resulting dermatitis. Therapeutic remedies have been legion, and many suggestions for prevention have been made. Some success in prevention has been reported following the oral administration of a diluted tincture of the plant, in accordance with the suggestion of Schamberg,³ and experiments are being made as to the efficacy of an extract⁴ for oral administration. In some persons, immunity has been produced by the injection of an extract of the plant each year before possible exposure.⁵

More recently, Schwartz, Warren and Goldman⁶ have recommended a preventive cream. Sodium perborate was added to a vanishing-cream base, and the mixture applied to the skin before exposure to the leaf. The volunteers on whom the fresh leaf was rubbed after the cream was applied did not develop any irritation. Only a few persons have thus far been tested, but the method deserves further trial by those who may be exposed to the plant. So far as is known, the effect of the paste on exposed persons has not been determined. This work resulted from an attempt to find a substance that would decompose or split up the complex chemical, urshiol, which is the active principal of the plant. Potassium permanganate will render the toxic agent inert, but discolors the skin; hence a search was made for a colorless preparation. This new method is relatively simple but must be used before every period of possible exposure. Although this is a handicap, any method that will prevent the dermatitis can well earn the praises of the many sufferers who are sensitive to this plant.

MEDICAL EPONYM

GRUBER-WIDAL TEST

The Gruber-Widal test is based on the theoretical investigations of Max von Gruber (1853-1927) of the Department of Hygiene in the University of Munich, and their practical application by Fernand Vidal (1862-1929). Von Gruber, in an article entitled "Theorie der activen und passiven Immunität gegen Cholera, Typhus und verwandte Krankheitsprocesse [Theory of Active and Passive Immunity to Cholera, Typhoid Fever and Related Diseases]," which appeared in the *Munchener medizinische Wochenschrift* (43: 206, 1896), concludes:

By means of intraperitoneal inoculation with the killed culture of the vibrio of cholera, . . . the typhoid bacillus, and the colon bacillus, a high-grade and persistent immunity may be achieved in the guinea pig. . . . Antibodies are present in the blood and body fluids of the immunized animals. . . . The essential effect of the antibodies of the body fluids in these immunized animals consists in a destructive alteration of the enveloping structures of the bodies of the bacteria. This is shown by the fact that bacteria treated with these fluids become viscid, collect in large clumps and lose their individual motility.

Widal, in his article "Sero-diagnostic de la fièvre typhoïde [The Serum Diagnosis of Typhoid Fever]," which appeared in the *Bulletins et mémoires de la Société médicale des hôpitaux de Paris* (13: 561-566, 1896), after acknowledging his debt to Pfeiffer, Koll and von Gruber, says:

We present a new method, which makes possible the diagnosis of typhoid fever simply by observing the effect of the patient's serum on a bouillon culture of Eberth's bacillus. . . . A small amount of blood . . . is collected under aseptic precautions; . . . the serum is decanted, and several drops are added to a tube of broth in the proportion of one part of serum to ten or fifteen parts of bouillon. . . . After twenty-four hours, the bouillon is only faintly clouded; a few floccules have settled to the bottom, and a whitish, rather heavy suspension is visible throughout the length of the tube. . . . Inspection of the tube is not enough; microscopic examination is also necessary. . . . The bacilli, instead of wriggling all over the preparation . . . are seen to be grouped, agglutinated together. . . . The diagnosis may also be made more quickly. . . . It may be so apparent that six drops of serum mixed with 4 cc. of culture, after being kept at room temperature for two or three hours, will produce the characteristic clumping to the naked eye. . . . The diagnosis must never be made until after microscopic examination. . . . If one drop of serum is added to ten drops of a culture of Eberth's bacillus, one may almost immediately demonstrate the characteristic bacterial agglomeration under the microscope.

MASSACHUSETTS MEDICAL SOCIETY

SPECIAL MEETING OF THE COUNCIL

A special meeting of the Council of the Massachusetts Medical Society will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, April 9, 1941, at 10:30 a. m., by vote of the Council on February 5, 1941, as provided in Chapter IV, Section 1, of the by-laws.

Business: To consider various changes in the by-laws recommended to the Council at its meeting on February 5, 1941 by the Committee on Medical Education and Medical Diplomas and by the Committee to consider new officers and by-laws.

Incidental business.

ROBERT N. NYE, *Secretary pro tempore*.

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting luncheon will be served immediately after the meeting.

HEART DISEASE IN PREGNANCY

Between 1 and 2 per cent of pregnant women in this country have organic heart disease. Many of these have minor valvular lesions of little consequence, and others have such severe cardiac damage as to involve considerable risk to the life of the mother and even more to the fetus. In addition to the relatively small group with clear-cut organic disease of the heart, there is a much larger group in whom the appearance of disease is simulated by functional systolic murmurs that may be quite loud and by symptoms such as dyspnea, palpitation and ankle edema that are not uncommon in normal pregnant women. It is the first task of the attending physician to determine, if possible, whether or not organic heart disease is present. A convenient rule of thumb is that organic heart disease exists if any of the following features are present: a diastolic murmur, definite cardiac enlargement, or auricular fibrillation. If these features are absent, the heart may be regarded as practically normal. There are exceptions to this rule, but they are rare.

Having satisfied himself that organic heart disease is present, the physician attempts to evaluate the degree of cardiac disability. The question

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

whether a given cardiac patient will be able to go through to term successfully can usually be answered better by the patient herself than by the intensity of the murmurs or other physical findings. If she gives a history of previous heart failure, she is likely to go into failure again before she reaches term. The older patients are, in general, poorer risks than the younger. Dr. Burton Hamilton has pointed out that heart failure occurs twice as often in women over thirty-five as in women under thirty-five years of age. Complications such as hypertension or pulmonary infection also add to the gravity of the prognosis. If the patient is young and her heart has never failed and there are no complications, the chances are good that she will carry her pregnancy through to a successful termination, regardless of the valvular lesion.

In considering the problem of the management of the heart patient in pregnancy, due weight should be given to recent work regarding the extent to which the gravid uterus burdens the circulation. Clinical and physiologic studies at the Boston Lying-in Hospital and elsewhere indicate that the work of the heart is increased about 40 to 50 per cent during pregnancy. Of great practical significance is the accumulated evidence that the peak of increased cardiac work is reached not at term but about one month before term. The subjective "lightening" observed by so many patients at this time appears to be associated with objective evidence of an easing of the load on the circulation, the cardiac output actually approaching normal before delivery.

In the light of this evidence, the practice in some clinics has changed from emptying the uterus as soon as a viable baby could be obtained to allowing the cardiac patient to go to term if possible. This policy has resulted in a decline in both maternal and fetal mortality.

The physical activity of all patients with organic heart disease should be rigidly restricted throughout pregnancy. They should have assistance in their household duties, and they should be instructed to go to bed at the first sign of a respiratory infection. They should be carefully examined for early signs of heart failure at least every two weeks during the first half of pregnancy, and once a week thereafter. The earliest sign of failure is usually *persistent* rales at the lung bases, which may appear before the patient herself is aware that anything has gone wrong. Once failure has set in, the patient should be put to bed and kept there under hospital conditions of absolute rest until she is delivered. If failure comes

on during the first four months, it is extremely unlikely that the patient can be brought to term with a living baby, and it is well to advise interruption at this time. If failure does not occur until the sixth month or later, every effort should be made to tide the patient over with digitalization and absolute rest until she goes into labor, and then to let her deliver spontaneously from below. It is not advisable to give digitalis unless failure is present or appears to be impending. Surgical interference should never be attempted while the patient is in failure. The maternal mortality under such conditions is 50 per cent. If the uterus is not interfered with and severe congestive failure persists, the patient is apt to go into labor spontaneously, and it is the lesser risk to allow her to do so with the operator standing by to make the second stage as brief as possible as soon as the cervix is fully dilated.

So far as anesthesia is concerned, particular care should be taken to avoid anoxia and excitement. Ether and oxygen anesthesia in skilled hands is very satisfactory.

Under careful supervision the maternal mortality in heart disease can be reduced to nearly 2 per cent.

COMMITTEE ON STATE AND NATIONAL LEGISLATION

House Bill 1222, a bill proposing a separate board of registration for chiropractors will soon be brought before the House of Representatives.

This type of bill always has a good deal of active support, and your Committee on State and National Legislation strongly urges all fellows to write to their representatives and senators, asking them to work and vote against the bill.

The following bill is scheduled for hearing at the State House during the week of March 17:

March 18

H. 1618 (Public Health). Petition of D. N. Potter and others that certificates of vaccination or nonvaccination shall no longer be required as a prerequisite to attendance in the public schools or other institutions of the Commonwealth. The perennial antivaccination bill. *Opposed.*

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 16:

BERKSHIRE

Thursday, March 20, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. Dermatitis and Ec-

zema Instructor Maurice M Tolman Harry
G Mellen, *Chairman*

BRISTOL SOUTH (Fall River Section)

Tuesday, March 18, at 4 30 p.m., at the Union Hospital, Fall River Recent Advances in Medical Therapeutics Instructor Clifford L Derick
Howard P Sawyer, *Chairman*

FRANKLIN

Thursday, March 20, at 8 00 p.m., in the Library of the Franklin County Public Hospital, Greenfield Nutritional Deficiencies and the Uses of Preparations of Vitamins Instructor Harold J Jeghers
Halbert G Stetson, *Chairman*

HAMPDEN

Wednesday, March 19, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Chemotherapy in the Treatment of Gonococcal Infection Instructor Sylvester B Kelley Alfonso A Palermo,
Chairman

HAMPSHIRE

Thursday, March 20, at 4 15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton Technique and Treatment of Primary, Secondary and Tertiary Syphilis Instructor William P Boardman Robert C Byrne,
Chairman

WORCESTER

Tuesday, March 18, at 8 30 p.m., in the Nurses' Home of the Milford Hospital, Milford Technique and Treatment of Primary, Secondary and Tertiary Syphilis Instructor C Guy Lane Joseph Ashkins, *Chairman*

WORCESTER NORTH

Friday, March 21, at 4 30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg Obstetric Infections Diagnosis and Treatment Instructor Judson A Smith George P Keaveny, *Chairman*

DEATHS

FRANCIS—CARLETON S FRANCIS, M.D., of Brookline, died March 8 at Kerrville, Texas. He was in his seventy sixth year.

Born in Brookline, he attended Harvard University and received his degree from the Harvard Medical School in 1897. He studied abroad for a year and then opened an office in Brookline.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and two sons survive him.

WETHERELL—BRYANT D WETHERELL, M.D., of Boston, died March 5. He was in his fifty third year.

Dr Wetherell attended Williams College and received his degree from Harvard Medical School in 1918. He was a fellow of the Massachusetts Medical Society and the American Medical Association, and was on the staff of the Massachusetts General Hospital.

His widow survives him.

MISCELLANY

THE MEDICAL LIBRARY ASSOCIATION

Every physician who recognizes the important place that medical literature has in the rapid march of scientific progress will look with approval and gratification upon the splendid work of the Medical Library Association. Composed of all medical libraries of any consequence in the United States, and many in Canada and abroad, this group has long been committed to the development of medical libraries and to the better organization of library resources so that they may be of the greatest possible help in the furtherance of medical research and achievement. It goes without saying that the individual libraries and librarians that constitute the larger part of the membership have been of tremendous assistance to physicians and others in their daily investigations and experiments, hence, the association merits the support of physicians.

Organized some forty three years ago, the Medical Library Association has become preeminent in its field and enjoys a well earned international reputation. Dr G M Gould, who was its founder, was also its first president. Succeeding him in this office were such illustrious men and women as Osler, Chadwick, Jacob, Dock, Musser, C Perry Fisher, J C Wilson, F R Packard, Lt Col C C McCulloch, H L Taylor, Brown, Ing, Garrison, Farlow, Barker, Wyde, Tice, Ruhrah, Malloch, Steiner, Miss M C Noyes, C Frankenger, W W Francis and J F Ballard. Colonel Harold W. Jones, of the Army Medical Library, is now president.

Perhaps the most outstanding activity of the association is its maintenance of an exchange—a clearing house through which members may exchange their duplicate books and journals with other libraries, so that they may find a place where they are needed. Every member library has profited by this mutually helpful arrangement, and frequently member institutions are able to complete series of great value.

Libraries having at least 1000 volumes of medical interest and open for regular use with a full time librarian on duty are eligible for membership.

Officers and members of the association have worked untiringly toward the achievement of its numerous objectives, but it is admitted that support from dues alone is insufficient, owing to the limited number of medical libraries that are eligible for membership. As a consequence, the membership committee of the association is endeavoring to attract a larger number of supporting members from among its physician friends and others. A supporting member may be any person interested in medical libraries and medical literature. The dues are \$5.00 annually, this includes the interesting quarterly *Bulletin of the Medical Library Association*. A supporting member has the privilege of attending the annual meetings and of making suggestions for the association's program. Dr A H Sanford, of the Mayo Clinic, recently has contributed an article (The supporting member *Bull M L A* 28 100-104, 1939), which points out some of the advantages accruing to the physician who participates in the work of the association through this type of membership.

The Medical Library Association is striving to create a stronger bond with the medical profession and to derive mutual benefit from a better understanding of its manifold problems. Further information and application blanks may be had from Miss Louise Williams, Chairman, Membership Committee, Old Capitol Jackson Mississippi.

REPORT OF MEETING

BOSTON ORTHOPEDIC CLUB

A regular meeting of the Boston Orthopedic Club was held at the Boston Medical Library on December 18, 1940. Dr. Fritz Teal, of Lincoln, Nebraska, spoke on the Orr method of treating compound fractures. The speaker recounted how Dr. Orr decided on his procedure. In studying war wounds in World War I, he concluded that immobilization of a fractured limb was best carried out by plaster of Paris and that the true goal of asepsis is the exclusion of infection rather than the discovery of effective bactericides. This original principle of Lister has often been lost sight of in many methods of caring for infection, such as the Carrel-Dakin treatment.

The Orr method consists in following the first fracture principles of good apposition and adequate immobilization. The fundamental aseptic principle of excluding further infection is carried out. And finally the technic of Paré—whereby the natural reparative properties of the body are allowed to carry out their work—is adopted. It is a simple, effective, timesaving method that may be employed in already infected as well as new cases. Dr. Teal stated that there is a decrease in the time of healing, better apposition, lack of introduction of bacteria by irrigation, failure of proteolysis and absence of evaporation and dehydration. It is not applicable to all cases, a noteworthy exception being those in which there is extensive soft-tissue damage.

In reviewing statistics of World War I, Dr. Teal remarked that 50 per cent of all fractures of the femur, tibia and humerus resulted in disability eight years later. He stated that although the use of Thomas splints and Dakin irrigations resulted in some improvement, the results still fell short of the optimum.

In contrast were cited the results in the recent Spanish War, where two different reports indicated a mortality of only about 3 to 5 per cent in cases of compound fracture. Furthermore, the number of amputations necessary was only 4 out of 1100 in one report and none in 5000 in the other. That gas gangrene is definitely decreased in the Orr treatment, even when bacteria may be demonstrated, was substantiated by the finding of this complication in only 1 of the 5000 cases thus treated.

Dr. Teal reviewed briefly the technic of the Orr treatment. The injured extremity is thoroughly cleaned with soap and water and then prepared with iodine around the lacerated area only. The patient is placed on a fracture table, although this is not necessary, and proper alignment is obtained by traction and assured by fluoroscopic examination. The field is then draped and widely débrided. Irrigation was found necessary only rarely. The opening is enlarged as necessary. Fixation pins are placed as soon as cleansing and débriding are complete. No sutures are employed. Vaseline gauze is then placed in the wound, although any similar type of dressing may be used. A sterile dressing, sheet wadding and plaster of Paris are then applied, and there is rarely any reason to remove these for inspection, for the clinical chart will furnish the necessary clues to infection. After four to six weeks a window is made in the cast under aseptic precautions. The cast may be changed if secondary infection is present. It has been found that the wound is usually healed by the time of fracture healing.

At the Orr clinic, good results are obtained in 84 per cent of cases, despite the fact that almost half the patients are referred to the clinic after previous treatment. In 6

cases, amputation, although advised elsewhere, was not performed, and 5 of these patients made a satisfactory recovery.

The discussion was opened by Dr. Henry Marble, of the Massachusetts General Hospital, who defended the use of the Thomas splint and the Carrel-Dakin treatment as carried out during World War I. The patients always arrived at the base hospitals in good condition, the wounds were secondarily sutured, and the dressings were neither painful nor time consuming. One objection to the Orr method was that plaster does not hold the fracture well, especially when it involves the tibia and femur, with the result that traction must often be resorted to. The incorporation of pins has corrected this, it was admitted. Other points not considered in the Orr treatment are the function of neighboring joints and the atrophy of muscle.

Dr. Otto Hermann, of the Boston City Hospital, emphasized that any method properly carried out usually gives good results. Sherman, of Pittsburgh, over a period of twenty-three years treated over 11,000 cases by débriding, irrigating with Carrel-Dakin solution and fixing by external or internal methods, as indicated. Of 630 fractures of long bones there were 23 amputations, no cases of sepsis and 2 deaths—from embolus and shock. Dr. Hermann concluded that the Orr method may prove efficacious in wartime, but that Sherman's methods seem better when time and space are available. At the Boston City Hospital, primary suture is carried out if the wound is less than eight hours old, and if a careful history shows that the place and manner of injury are not contraindications to such a procedure. A soap-and-water scrub is carried out for fifteen to twenty minutes. Irrigation is used only after the wound edge has been débrided. The type of fixation depends on the demands of the individual patient.

Dr. William Rogers, of the Massachusetts General Hospital, reiterated the importance of immobilization and surgical nonintervention. He believes, however, that vitalium plates, especially when combined with traction, afford better immobilization than plaster, even when pins are incorporated; this also allows uninterrupted observation. The wound is left alone until walled off by granulation tissue, whether promoted by vaseline gauze or some other means. Bone chips should be left in place. Chemotherapy is employed whenever indicated.

Dr. Carl Walter, of the Peter Bent Brigham Hospital, stated that no one routine was carried out at that institution, the usual method being to cleanse thoroughly, carry out primary suture when possible and treat the wound as an ordinary fracture. The few deaths were from indirect causes, and amputations only for gas gangrene. Dr. Walter emphasized that Lister was primarily interested in asepsis as opposed to antisepsis, one of his first reported cases being a compound fracture that received treatment essentially similar to the Orr method. Lister stressed the importance of nonintervention and the wide spacing of any dressings, and then the changing of only the exterior ones until healing has taken place.

The discussion was continued by Dr. Champ Lyons, of the Massachusetts General Hospital, who presented his views on chemotherapy, especially as related to anaerobic infection. Anaerobic bacteria are relatively frequent contaminants, and the duration or mode of accident does not ensure against their presence. Statistics are as yet inconclusive as to the effect of the newer chemicals on the gas-forming organisms or their relative therapeutic effects. Sulfathiazole, it has been demonstrated at Johns

Hookins Hospital, delays sound wound healing, and inhibits the growth of epithelium and fibroblasts in a concentration of 20 mg per 100 cc. Sulfanilamide, on the other hand, has occasioned no trouble with healing in concentrations as high as 200-400 mg per 100 cc. Key has used sulfanilamide powder in wounds covered only by skin. Eight grams will result in a blood stream level of 12 to 14 mg, which rapidly declines unless auxiliary oral therapy is started in twelve hours. Sulfapyridine experimentally is more effective against established gas-bacillus infection than sulfanilamide, especially when serum is being used. Since it requires too long to determine which bacterium is at fault, the use of trivalent antiserum was advised. The initial therapeutic dose should be 120,000 units of *Clostridium welchii* and *C. oedematis* maligni antitoxins and 30,000 units of that for the other gas-forming bacilli. This is the amount contained in four therapeutic vials, and should be followed by two vials every eight hours until improvement occurs. A sulfapyridine level of 8 mg per 100 cc. should be maintained.

In closing the discussion, Dr Tenl explained that Dr Orr had been using pins for fifteen years, and that this was considered simpler than, and as effective as, plating. The latter was conceded to be satisfactory if left open. Primary suturing was found to invite too much trouble, especially since the wounds heal as soon as the fracture and can be improved by secondary plastic operations, if necessary.

NOTICES

MEDICAL AND SURGICAL SUPPLY COMMITTEE

It will help England greatly in the care of victims of bombing raids and help England prepare for the coming invasion, if physicians in this country will give discarded or superfluous surgical instruments or surgical dressings.

Any such material should be sent to the Medical and Surgical Supply Committee, 420 Lexington Avenue, New York City.

COMMUNITY NURSING COUNCIL OF BOSTON

The third annual meeting and luncheon of the Community Nursing Council of Boston will be held at Perkins Hall, Women's Educational and Industrial Union, 264 Boylston Street, Boston, on Thursday, March 27, at 12:30 p.m.

PROGRAM

Business meeting
Nursing in National Defense. Miss Stella Goostray, R.N.
The Federal Census of Registered Nurses. Miss Helene G. Lee, R.N.
Progress of Legislation. Miss Margaret Dieter, R.N.
The charge for luncheon will be 75 cents. Reservations sent to the Community Nursing Council of Boston, 80 Federal Street, Boston, should be made by Monday, March 24.

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in the auditorium of the Carney Hospital on Monday, March 24 at 11:30 a.m.

PROGRAM

Nasal Allergy. Dr. William T. Holey
Review of Cases Requiring Hysterectomy at Term. Dr. William J. McDonald.
Acute Cor Pulmonale. Dr. Sylvester McGinn.
Surgical Diseases of the Breast. Dr. John W. Spellman.
Physicians and medical students are invited to attend.

BOSTON LYING IN HOSPITAL

There will be a meeting of the Journal Club of the Boston Lying in Hospital on Wednesday, March 19, at 8:15 p.m. Dr. Edward G. Waters, assistant clinical professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, will speak on Local and Spinal Anesthesia in Obstetrics.

Physicians and medical students are cordially invited to attend.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

There will be a meeting of the New England Society of Physical Medicine at the Hotel Kenmore, Boston, on Wednesday, March 19, at 8:00 p.m. A council meeting at 6:00 p.m. will be followed by an informal dinner in the Empire Room at 6:30 p.m.

PROGRAM

Symposium on the Treatment of Arthritis
The Parenteral Use of Amodoxyl Benzoate. Dr. Albert G. Young.
Methylol Iontophoresis. Dr. Wilmot L. Marden.
Diathermy. Dr. William D. McFee.
X-ray. Dr. Herman A. Osgood.
Discussion by Dr. A. Carleton Potter.

All members of the medical profession are cordially invited to attend.

NEW ENGLAND HEART ASSOCIATION

There will be a meeting of the New England Heart Association on Monday, March 24, in the pathological amphitheater of the Boston City Hospital at 8:15 p.m.

PROGRAM

Familial Occurrence of Congenital Cardiac Anomalies. Drs. Gerald C. Walker and Laurence B. Ellis.
The Influence of the Climacteric on the Course of Organic Heart Disease. Drs. Burton E. Hamilton and Paul Kunkel.
Paroxysmal Ventricular Tachycardia. A study of 33 cases. Dr. Conger Williams.
The Significance of the Wandering Auricular Pace-maker. Dr. Andrew M. Burgess, Jr.
The Occurrence of Sinus Arrhythmia in Association with Acute Myocardial Infarction. Dr. Carey M. Peters.
Nonarterial Disorders Simulating Diseases of the Peripheral Arteries. Dr. Edward A. Edwards.
Interested physicians and medical students are cordially invited to attend.

NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held at the Children's Hospital on Thursday, March 20, at 8 p.m.

PROGRAM

Survey of the Bacteriological Laboratories in Massachusetts. Dr. Leo Ranc.

Co-operation between the Pathologist and the Embalmer. Mr. Austin W. Martin.

What Deaths Are Medico-Legal? Dr. William J. Brickley.

Business meeting.

NEW ENGLAND OTO-LARYNGOLOGICAL SOCIETY

The regular spring meeting of the New England Oto-Laryngological Society will be held on Wednesday, March 19, at the Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston, at 4 p.m. The evening program will be devoted to a symposium on "The Management of Some of the Complications Arising from Acute and Chronic Otitis Media." Discussion will follow by Drs. Harold Tobey, Charles T. Porter, Maxwell Finland, Champ Lyons, W. Jason Mixter and Charles S. Kubik.

NORFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Norfolk District Medical Society will be held at the Hotel Puritan, Boston, on Tuesday, March 25, at 8 p. m.

PROGRAM

Business.

Nutritional Deficiencies and the Uses of Preparations of Vitamins. Dr. Harold J. Jeghers.

Discussion.

Collation.

26TH DIVISION MEDICAL SERVICE

The 26th Division (Massachusetts) is rapidly filling to war strength with men from almost every walk of life. One outstanding numerical exception has been the representation of the Massachusetts Medical Society.

More qualified physicians are required to fill vacancies in the Division Medical Service. The requirements are: a medical diploma from a Class-A School, a minimum of one year's internship and a sound physique. The candidate must also be no more than thirty-five years of age. Previous military training is desirable but not essential.

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS AND AMERICAN INDUSTRIAL HYGIENE ASSOCIATION

The annual meeting of the American Association of Industrial Physicians and Surgeons and the American Industrial Hygiene Association will take place from May 5 to 9 at the Hotel William Penn, Pittsburgh, Pennsylvania. Industrial health specialists from all parts of North and South America will attend. An intensive graduate course in present-day industrial health problems will be presented. May 5 will be devoted to a series of dry clinics in industrial medicine and surgery at the Mercy Hospital. For detailed information write to Mr. A. G. Park, executive secretary, 540 North Michigan Avenue, Chicago, Illinois.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MARCH 16

MONDAY, MARCH 17

12:15-1:15 p.m. Clinicopathological conference. Peter Bent Brigham Hospital amphitheater.

TUESDAY, MARCH 18

*9-10 a.m. Syphilis and the Spinal Fluid. Dr. W. A. Hinton. Joseph H. Pratt Diagnostic Hospital.

*12 m. Asthma: Its treatment. Dr. Francis M. Rackemann. South End Medical Club. Headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston.

12:15-1:15 p.m. Clinicoroentgenologic conference. Peter Bent Brigham Hospital amphitheater.

WEDNESDAY, MARCH 19

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*12 m. Clinicopathological conference. Children's Hospital.

4 p.m. New England Oto-Laryngological Society. Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston.

BOOK REVIEWS

Rose and Carless Manual of Surgery. Sixteenth American edition. Edited by William T. Coughlin, MD. From the sixteenth English edition by Cecil P. G. Wakeley, DSc., FRCS, FRSF, FRSA, FRACS, and John B. Hunter, MC, MChir (Cantab.), FRCS 8°, cloth 1656 pp., with 1034 illustrations and 30 colored plates. Baltimore: Williams and Wilkins Company, 1940 \$9.00

According to the author's preface, this ponderous text—it weighs 6½ pounds—has been thoroughly revised and the first eight chapters have been entirely rewritten. These chapters discuss general and specific infections, inflammation and repair, ulceration, gangrene, wounds, tumors, hemorrhage and shock. It seems reasonable to examine them to determine how much new material has found its way into the book.

Seven pages are devoted to the subject of shock, and the following statements appear in the text. All observers are agreed that the constant feature [of shock] is the depression of the blood pressure from the normal systolic pressure of 110 to 120 mm of hemoglobin to 50 or below.

An estimation of the color index of the blood may help [in diagnosis], since it is normal in pure shock, but is lowered following hemorrhage. The only reference to transfusion in the treatment of shock is as follows: "The actual transfusion of blood is often useful, but may be disappointing in its effect. It is most valuable in cases of shock associated with severe hemorrhage where the patient's condition is aggravated by anoxemia from the lowered hemoglobin. In pure shock the loss of blood volume is a loss of the fluid portion of the blood and transfusion in these cases is of less value than the use of intravenous saline. The hemoglobin content of the blood may be taken as a guide, in shock a fall of hemoglobin below 70 per cent would form an indication for a blood transfusion."

In regard to the treatment of wounds, it is stated, "Tincture of iodine, either full strength or diluted half with 95 per cent alcohol, is in very general use for the first antiseptic treatment of wounds. The excess is removed from the wound by pouring in alcohol."

In the care of septic joints, following drainage, "the essential element is to urge, or if need be coerce, the patient into moving the joint actively, however painful it may be."

The progressive undermining ulcers due to microaerophilic streptococcal infections are described as gangrene of the skin following operation, but there is no recognition of the extensive contributions that have been made in recent years to the etiology or therapy of these conditions. Although innumerable pharmaceutical preparations are recommended in treating various conditions, zinc peroxide finds no place in the index, and is referred to only once in the text in connection with the treatment of actinomycosis. Sulfanilamide is given nine references in the index, six of them to page numbers not present in the book. The remaining three briefly dis-

cuss the use of the drug in streptococcal and gonococcal infections, with a footnote reference to articles by the staff of the Wellcome Research Laboratories in the *Lancet* in 1936 and 1937.

Postoperative proptitis today is very rare, since oral sepsis is always treated before any abdominal operation is contemplated. Treatment should be prompt, incision and drainage being required.

These quotations have been selected deliberately to emphasize the wide divergence that apparently exists between American and English teaching in surgery, and to point out how difficult it is to find a text that can be carried through numerous editions and still be up to date, with elimination of antiquated teachings and inclusion of new material. Similar quotations and omissions could be culled from most of the other chapters. Differences in terminology further complicate the picture and confuse the student. Thus, for example, benign giant cell tumor of bone is described as myeloma or osteoclastoma. In the treatment of osteogenic sarcoma, the authors state that x-ray treatment alone often causes a disappearance of the tumor, but recurrence is the rule.

Nearly 400 pages are devoted to orthopedic problems and diseases of bones, joints, and tendons. Superficial inspection of this section reveals an illustration of Colles fracture in a cast in the cock-up position, and a bone plate applied in reduction of a fractured femur, held in place with screws which extend only to the medullary cavity. The use of a pylon following amputation is condemned, there is apparently no appreciation of the mechanism of Volkmann's contracture, and passive movements of joints are strongly recommended in the restoration of function following injuries.

It is perhaps unnecessary to bring up more examples of omissions, inaccuracies and errors in the book. Some of the sections are sound. There are numerous illustrations and for the most part they are helpful in illuminating the text. In summary, however, it is the reviewer's opinion that a student would be ill advised to acquire or to depend on this text.

Juvenile Delinquents Grown Up. By Sheldon and Eleanor Glueck. 8°, cloth, 330 pp., with appendixes A, B and C and 85 tables. New York: The Commonwealth Fund, 1940 \$2.50.

This is unquestionably one of the most important objective and scientific discussions of juvenile delinquency to appear in recent years and gives the Gluecks first rank among the criminologists of the world. The reader may recall that in 1934 they published *One Thousand Juvenile Delinquents* a follow up study to determine the effectiveness of treatment.

In this book the authors make a painstaking and searching study of the same delinquents for the second and third five-year periods, directing their attention to such questions as, What has happened since? Have the delinquents gone from bad to worse, or has the picture brightened? How can one account for the changes in behavior? How far can delinquency be predicted? The thoroughness and ingenuity employed in ferreting out many of these elusive characters make interesting reading and document one angle of the Gluecks' scientific thoroughness.

The book consists of twenty-two chapters, it discusses the characteristics of delinquents follows them through the three periods and compares reformed and unreformed the young and the old and the serious and the minor offenders. The book makes a strong case for the possibility

of scientific prediction if judges, parole officers and boards would only begin the experimental use of the tables furnished.

With the passage of years there has been a steady diminution in the number of youths who continue to be offenders. By the age of twenty-nine almost 40 per cent have ceased to be criminals. Even among those who continued their criminal careers, significant improvement was noted. However, the chief cause of the improvement was not the penologic treatment but a natural process of maturation. For, regardless of the age of the offenders at the time delinquency began, it ran a fairly steady and predictable course. There is a marked resemblance in delinquent or criminal behavior at a point equidistant from the onset of misconduct, regardless of the age of the persons concerned.

Comparison of delinquents who reformed within fifteen years with those who had not reformed showed that the former had better heredity and more wholesome environment than the men who continued criminal careers. Those who reformed before twenty-one possessed both better innate equipment and environmental advantages. The more serious offenders had a worse congenital equipment and were reared in even less favorable circumstances than those responsible for minor offenses.

Four conduct types are distinguished, and prediction tables are offered that should make sentencing more intelligent if judges would experimentally sentence every other offender on the basis of it and study the results.

The authors conclude, "It is not so much arrival at any particular age-span . . . as the achievement of a degree of maturity, that makes for social adaptation on the part of former delinquents." Delinquents are primarily infantile; they mature much more slowly. Too often they reform by wearing out. As they get older they resort to minor crimes. They lose courage and do not have the physical equipment for more daring escapades.

This book will repay study by physicians, psychiatrists, sociologists and counselors of youth. It should be "must" reading for criminologists, judges and members of parole boards.

The Treatment of Diabetes Mellitus. By Elliott P. Joslin, M.D., Sc.D.; Howard F. Root, M.D.; Priscilla White, M.D.; and Alexander Marble, M.D. Seventh edition, thoroughly revised. 8°, cloth, 783 pp., with 117 tables. Philadelphia: Lea and Febiger, 1940. \$7.50.

This familiar and valuable treatise now appears in its seventh edition under the coauthorship of Drs. Joslin, Root, White and Marble. The revision of this study of 18,000 of their own cases, as well as bringing the ever-enlarging literature in this field up to date, is a task of no mean proportions, but it has been done thoroughly and effectively since the appearance of the sixth edition in 1937.

The increased frequency of allergic phenomena since the introduction of protamine insulin has led to a new chapter on allergy in diabetes by McDaniel, and the increased interest in hyperinsulinism has led to a chapter on this subject by Marble. A most valuable chapter is that on the physiology of diabetes, revised by Marble, which includes references to all the newer developments in this field, including the important work of Houssay, Young, Himsworth and many others.

There has been almost no important change in the treatment of diabetes in the last three years, but the study of the cases that have been treated with protamine insulin

for three years has led to a more standardized use of this important therapeutic agent. A diagrammatic outline of standard treatment such as appears on page 288 is the result of the observation of many thousand cases. Little has been changed in diet therapy, but the newer knowledge of vitamins has not been neglected and, in fact, appears in this volume in a summarized form that is most convenient, entirely apart from its value in treating diabetic patients.

Coma is still considered to be present whenever the carbon dioxide content is below 20 vol. per cent, whether or not the patient shows any disturbance of consciousness, although this method of classification has been the object of criticism from several sources. Whatever criteria are used, however, the mortality rate for acidosis cases treated by these authors remains a challenge for others to equal.

Dr. White's work with pregnant diabetic patients, particularly the prolan studies and estrin and progestin therapy carried on in conjunction with Smith and Smith, is most interesting, and the results of this treatment are most encouraging. Whether these results have been confirmed in other clinics is not stated.

The volume remains the standard work on diabetes mellitus.

Rheumatic Fever: Studies of the epidemiology, manifestations, diagnosis and treatment of the disease during the first three decades. By May G. Wilson, M.D. 4°, cloth, 595 pp., with 47 illustrations, 76 figures, 81 tables and 31 charts. New York: The Commonwealth Fund, 1940. \$4.50.

Of the economic importance of rheumatic fever in this part of the world there is no question whatsoever. An increasing amount of study has lately been devoted to it—Dr. Wilson herself has been interested in the subject for more than two decades. Although a great deal has been learned, there still remains more that has not. The most elaborate treatise of today, therefore, can represent only a sort of stocktaking of knowledge. Such stocktaking, however, is extremely valuable.

The work begins with a brief historical summary; then follow chapters on epidemiology, including familial epidemiology, on etiologic hypotheses and on bacteriologic studies. Part II embraces general signs and symptoms, heart involvement and involvement of other organs and tissues, and bacterial endocarditis. Part III covers the age and type of manifestation at onset, prognosis and life expectancy. Part IV discusses the criteria of diagnosis and differential diagnosis, including the regression of physical signs, radioscopic examination of the heart, and the value of exercise tests, of the measurement of vital capacity and of electrocardiography. Part V is devoted to the care, management and therapy of the rheumatic child. The discussions throughout are not merely general; they are illuminated and reinforced by appropriate case histories and are illustrated with charts, plates and tables based on actual experience. Moreover there are extensive bibliographies.

It is not necessary that every doctor should own this book, not even every pediatrician or cardiologist. But it should be in every medical library, and in the libraries of all hospitals where research is undertaken. For such a book of reference often saves repetitious work, or better still, may serve as the steppingstone to new and even more definitive studies.

NUMBER 12

FOLK MEDICINE IN NEW HAMPSHIRE*

HAROLD D. LEVINE, M.D.

BRISTOL, NEW HAMPSHIRE

IN the small towns and villages and in the countryside of New Hampshire there still exists a vast heritage of medical folklore, most of which stems from the practices of the original English settlers and their Indian neighbors. Even in the minds of the "old folks" this storehouse of "simples, bitters and specifics," of medical superstition and voodoo, is all too vague. And the younger people know still less about the subject. The need for these homely remedies arose, of course, from the inaccessibility of medical care to the farmers, woodsmen and laborers living in remote country districts. But the advent of the country doctor, the increased use of the radio, newspapers and magazines, the founding of reading clubs, the automobile and the construction of more and better roads have made their further use unnecessary. Unless recorded now, all knowledge of this fascinating subject and interest in it may well be lost forever.

The country doctor, unlike the physician practicing in large cities, who treats a presumably more enlightened and sophisticated group, is in a peculiarly fortunate position to observe and record these traditional practices. I have undertaken to describe how the people of New Hampshire, particularly in the central portion, have treated and, to some extent, continue to treat disease at home. I have obtained most of the material directly from them, and many of the quoted passages are verbatim accounts of what they have said.

It is hoped and urged that country doctors practicing in others parts of our country make similar observations and thus help to preserve that body of our national culture called Americana.

RESPIRATORY INFECTIONS

Obviously these people were interested in treatment, not in diagnosis. They knew what their

symptoms were, and they wanted relief from them. If the patient had a sore throat it did not matter to him whether he had diphtheria, septic sore throat or just plain sore throat. What he wanted was relief.

Considerable merit was attributed to a gargle made by steeping equal parts of elm bark, white-oak bark, sumac berries and blackberry root. Many preferred a gargle containing a mixture of brake root and whisky. Others acclaimed the virtues of kerosene, either "outwardly" or "inwardly" or both, that is, it might be rubbed on the outside of the neck or swished about in the throat. Gold beads or a gold chain worn around the neck still has vogue in the prevention and treatment of sore throat—and is also said to be useful as a prophylactic against and treatment for goiter. A dirty or used dark stocking worn around the neck served as a moral if not physical deterrent against colds "going down into the chest." An alternative method still widely used is to bind to the neck at bedtime a red flannel bandage with thinly sliced salt pork and thinly sliced onions, the whole sprinkled with black pepper.

Closely related to sore throat was so called "canker." This apparently meant any membrane in the buccopharyngeal cavity, no matter what its cause. For this condition an infusion of gold-thread was used as a mouth wash. The use of this herb was known to the Indians.¹ Brake root or sage tea was similarly used. Amber beads were worn to prevent croup, Castanea (chestnuts), dried bumblebees in molasses or just plain urine was used to cure croup. Sugar added to moss obtained from the north side of a maple tree was regarded as an excellent cough sirup. So were a sirup made of yarrow or of red clover and a drink made of eclecampane (sunflower). Red clover was supposed to be especially effective in whooping cough. A concoction called "Rob" and containing elderberries enjoyed wide use in this region. Fifty years ago, many people in the neighborhood gathered herbs for the Shakers of Canterbury. One

*Read before the Merrimack (New Hampshire) County and Center District Medical Society on July 10, 1940.
†Liberarian of staff, Franklin Hospital.

Thomas Corbett, "a properly trained physician," joined them and made a cherry pectoral. His name is on the label of the old blown bottles of Canterbury sarsaparilla.²

For "colds" in general there was the familiar catnip tea or that made from dried elder blossoms and peppermint leaves, but the most spectacular medicine was hard cider with cayenne pepper *à la* red-hot poker. "Men folks used to take hard cider, heat a poker red hot, while heating sprinkle the cider with cayenne pepper, then run the red-hot poker plumb into the mug of cider, causing it to boil and foam. This was drunk down as soon as the poker was taken out."

The herb, thoroughwort, is also called "boneset," a name derived from its use in the severe form of influenza called "break-bone fever." Elder-flower tea was considered infallible in the early stages of influenza. If it did not work, "you just weren't early enough in using it."

With regard to tuberculosis, the following story, which appeared in the July, 1939, issue of the magazine, *Yankee*, is of interest.

"You must be Ned's boy," an old man said to me once. "I knew your father. Yes, I knew your great-grandfather and all his family, and I'm going to tell you something that will surprise you."

"You probably don't know it, but if a family is dying off of consumption, the disease goes no farther after one of the members of the family has been buried face down."

"I was at the funeral of your great-uncle John. He died of old-fashioned consumption just as other members of the family before him. I was one of several who made up our minds to stop the run of consumption in that family, so we stayed in the cemetery until the relatives had gone, then we lifted the casket from the open grave and turned it over. So your great-uncle John was buried face down, and it ended consumption in that family."

In my opinion the following story from New Hampton is even better. The two daughters of a prominent farmer, Marshall Bowen, both contracted consumption. They tried everything known at the time, and finally went to the village witch, who told them that one girl was past saving, but that when she died, they should cut her heart out and bury it by Dickerman Brook. This would prevent the death of the other daughter. Tradition is vague as to whether this dictum was followed, but the other girl died of the same disease.

In the treatment of any lung disease—from a simple "cold in the chest" to pneumonia—it was and is still considered essential that the patient be well greased. And the favorite remedy for this purpose is skunk's oil, although Vick's Vapo-Rub is now running a "strong" second. No amount of arguing will convince these people

that these greases only make the patient messy, smelly and uncomfortable: "Why any fool knows that the greases strike right into the lungs and make the cough looser."

Skunk oil is obtained by catching a skunk in the fall, when it is "nice and fat." It is carefully dressed, particular care being taken not to disturb the scent gland. After skinning and removal of the viscera and scent gland, the carcass is slowly baked in an oven so that the fats are not burned. The oil cooks out and is caught in a vessel. It is sometimes taken internally as well as externally. Although skunk oil is widely used in the Bristol region, the folks around Wolfeboro prefer to use a baked-bean poultice, and in the Franklin neighborhood the flap-jack poultice is popular.

CARDIOVASCULAR DISEASES

Pipsissewa had a particular vogue in the treatment of heart disease. This beautiful plant, also known as "heart's ease" and brought over from England, was used to heal disease of the heart as well as the "broken heart." And garlic was eaten for its reputed effect of preventing high blood pressure and hardening of the arteries.

The following "Old Woman's Sure Cure for Dropsy" is handed down from old Dr. Stillings of Concord: "Take a little garden selendine, a little pipsissewa, a little gill [ivy] run over the ground, green of alder and white of hen dung. Slowly simmered over a slow fire and taken in copious draughts, this will produce such slushes of water and slugs of turd as ever your eyes have beheld."

FEVER AND THE "WATER CURE"

Standard treatment for fever was the use of sage or catnip tea, tea of pink or white yarrow, or compound spirits of lavender and ether. I have sometimes had trouble getting patients to take water when they had a fever. This is possibly the effect of the old adage, "Stuff a cold and starve a fever." I once had occasion to advise a ninety-year-old codger with urinary infection to drink plenty of water. As I was driving off I could hear him protesting to his daughter: "I know his kind. He's one of them goddam cold-water doctors!" Interestingly enough, I later learned that a cult of "water doctors" had practiced in the region. The so-called "water cure," a "method of treating infirmity and disease," was introduced in Concord by Dr. Timothy Haynes about 1850. He enjoyed a good practice for a time but disposed of his "institute" to Dr. William T. Vail, who ran it for three years and then in 1855 moved to Franklin

and soon after to Hill, where the institution had its remaining life.³

Speaking of the water cure, the following story may be of interest. A family of Robinsons lived on the old mountain road to North Sanbornton. One of the children developed rickets, whereupon some rustic sage told the mother that the way to cure the child was to take him down to Palmer Spring in the vicinity, and to dip him in the water nine times. The baby survived the ducking and the rickets.

NOSEBLEEDS

To prevent nosebleed a piece of red woolen yarn or a piece of nutmeg strung through two holes was worn around the neck. For children, bloodroot was hung over the foot of the bed. If the preventive measures did not work or if the patient failed to take them, nosebleed could be treated with fresh blossoms of red trillium held to the nose. For bleeding in general and nosebleeds in particular, cobwebs were widely used. The fine powder obtained from the puff ball mushroom after it had gone to seed was reputedly an excellent quencher of blood.

A patient from Franklin confidently states that she knew someone who took red clover for a fibroid tumor,⁴ under that treatment the "fibroid tumor became benign."

GASTROINTESTINAL DISEASES

For "stomach trouble" the people along the Pemigewasset River used to gather bloodroot on Sumner Island. For "heartburn, dyspepsia or indigestion" they used to "chew one teaspoonful of whole white mustard seed followed with a glass of water." Sassafras, camomile, wormwood and burdock teas were also used for stomach disorders. But hearken to this sound bit of advice on "dyspepsia" from *The Family Doctor or Guide to Health* (Boston: H. B. Skinner, 1844) lent me by the beloved octogenarian Jewell sisters, of Hebron, "Abstain from medicine and live upon a sixpence a day, and earn it, or rise with the sun, saw wood for half an hour, and breakfast upon a crust of bread."

Lobelia ("puke weed") was used to make one vomit and thus "clear off the liver." This explains why the recent attempt to revive the use of this herb—in the form of lobeline sulfate—to cure the smoking habit was so unpopular. "Turkey dung bitters, warmed," were used for the "jaundices." The people around New London preferred ironwood bark in the treatment of jaundice. The leaves and flowers of liverwort (hepatites) so called from the resemblance of its leaves

to the lobes of the liver, were used as a milder remedy for disorders of the liver. This use of vegetable medicines by reason of their real or fancied resemblance to the disorder or the part affected, the so called "doctrine of signatures," was firmly believed in by the Indians and the old English herbalists. The idea was that, by the mercy of God, many of the herbs made for the service of mankind were stamped with their characters, so that they could be read at a glance. Thus a plant with a wormlike stem was used as a vermifuge, and one with hairlike processes was used in the treatment of baldness.

In this region if anyone says he is "sick," it means that he is nauseated. Another term for nausea was "turn sickness." This usage harks back to the English ancestry of these people. I am told that in England the word "sick" is never used to indicate the state of being "ill" or "unwell." Their English origin probably also explains the fact that many of the natives, particularly those living away from the towns, address physicians as "Mister" rather than "Doctor." At first this apparent lack of respect annoyed me, but it was later pointed out that in addressing me as "Mister" their intention was to pay me the highest compliment of which they were capable. In England, of course, the regular practitioner is referred to as "Doctor," and the surgeon or superphysician is called "Mister."

Spearmint was regarded as specific for the treatment of nausea. For constipation rhubarb and senna were used. But it is not so well known that warm thoroughwort tea and a medicine made from the inner bark of the oil nut (hickory) tree were similarly used.⁴ The bark of some tree imported from Peru was supposed to have a laxative effect when stripped downward, but an emetic effect if stripped upward!

Perhaps the most widely used remedy for the "disentery" (diarrhea, "intestinal flu," "the runs" or "the trots") was blackberry root. But the astringent properties of the steepleoak bush, "hard tack" (leaves, roots and flowers), strawberry blossoms, sweet fern leaves and oak bark were put to similar use. Smartweed was regarded as especially good for "summer complaint." The following "cure for the disentery" is taken from the account book (1828) of Henry Hilton Chandler of Haverhill, through the courtesy of his great granddaughter. "Take one quart of hardwood ashes and one half gill of hardsoot from the brick of the chimney. Put to three quarts of hot water. Take from one half to a wine glassful two, three or four times per day." And finally I have it on good authority that green apples were also used

for diarrhea—not a far cry from the present-day, apple-pulp diet.

EXANTHEMATOUS DISEASES

To ward off contagious diseases a camphor bag was worn around the neck. This was regarded as particularly effective against scarlet fever and measles. Braided flax prevented scarlet fever and mumps. It was believed, and the belief is still widely held, that once one has contracted an exanthematous disease—in its pre-eruptive stage—the “rash must come out” and “the quicker it comes out the better”; otherwise it would “strike in,” and no end of dire consequences would ensue. Housewives still boast of the remarkable ends they go to in order to “bring out” the measles rash. The sovereign measures to ensure this favorable turn of events were the drinking of hard cider, of snake-root and saffron tea or of the celebrated “nanny-goat tea.” It is easy to understand how the vasodilatory effect of cider might make a measles rash more obvious. “Nanny-goat tea” or “lamb tea” or “nanny-pill tea” is simply a brew of sheep’s droppings. It is not clear to me why this heroic remedy was not also used to “clear off the liver.” The exact method of bringing out a measles rash seems to vary in different parts of the country. In writing of the poor whites in Florida in *The Yearling*, Miss Rawlings has Ma Baxter give Jody a mullein tea for that purpose.

Mumps “were” kept from “going down” by tying several strands of flax around a girl’s neck or a boy’s waist. Note that I said “mumps were” not “mumps was.” In this region mumps, measles, pulse and so forth are all considered plural. There are even some who call mumps on one side a “mump.”

URINARY “STOPPAGE”

A newborn infant delivered a few years ago in Groton was alleged by its mother not to have urinated for over twenty-four hours. She put a small bag of salt over the lower abdomen of the child and urinary function was promptly established. Shall we credit this mother, who had never heard of Pfeiffer or his work, with an uncanny ability to employ osmotic forces? “Punkinseed tea” is also used for failure to urinate.

CURE OF AN “INFIRMITY”

A child in the Mailbox Hill district of New Hampton was born with a “fissure”—where I do not know. An old man told the parents how to cure it. They were to go out to the wood lot and split an ash sapling near a brook so that the gap ran from north to south and so that the baby

could be passed through the tree. This they did, and the child gradually outgrew his “infirmary.” The tree is still standing.

“SPRING TONIC”

A rapidly disappearing old New England institution is the well-known spring tonic or general “toner up” of the system, a real event in the family life. In the spring the mind of the housewife turned to simples and bitters to be ready with “relief and benefit” for all who might need them. From the neatly bagged and labeled herbs hanging from the cross braces of her attic or shed, she would select the appropriate ones to make her favorite spring tonic. This varied somewhat in form but never in its qualities of bitterness and woe. The tonic ranged from sulfur and molasses, sage and India molasses, rhubarb and dandelions, through pipsissewa, wormwood with or without vinegar, thoroughwort, flowers of elder, poplar bark mixed with burdock and aloes to bloodroot. Adults preferred their own tonics sweeter and were not averse to their containing spirits in varying proportions. Dandelion wine was the prime favorite.

The following “blood medicine” was used as a “spring purifier”:

¼ lb. Burdock root	¼ lb. Spikenard root
¼ lb. Sarsaparilla root	¼ lb. Red-clover blossoms
¼ lb. Yellow root	1 handful Hops
¼ lb. Dandelion root	

These were stewed in 4 quarts of water until all the strength was extracted; then strained, with enough sugar added to taste, and stewed down to a sirup, when a half pint of brandy finished it off and made it ready for a tablespoonful dose three times a day.⁵

RHEUMATISM

Rheumatism was prevented by always carrying a horse-chestnut in the pocket, the efficacy of this device being satisfactorily proved by the fact that, after a few years of constant transportation, the chestnut became hard and dark from the absorption of the “rheumatic germs,” which would otherwise have attacked the transporter. An alternative was to carry in the pocket the bone from a raccoon’s penis.

For the relief of “rheumatic” joint pains a tea of the leaves of Canada thistle was drunk. For joint pains or sprains lard was heated in a skillet and a cupful of oats was added. When the oats began to pop out, the lard was applied locally as hot as could be borne. A poultice of mullein leaves boiled in vinegar was used for sprained

ankles. Catnip also relieved painful swelling, when applied in the form of a poultice. One old recipe book says "common ground worms simmered in lard is very effective in relaxing sinews that have been drawn up by disease or accident." And one man treats cramps in his legs by turning his shoes upside down under the bed.

EYES, EARS, 'MUMING,' TEETHING AND WORMS

For 'weak' eyes, gold earrings were worn. A tea of dried rose petals was used to bathe sore eyes, and rose water is still an important constituent of many of our present day eye washes. For sore eyes in infants, warm breast milk was milked directly from the mother into the baby's eyes. From New Boston comes a report of the use of urine for inflamed eyes.

There were several well known treatments for earache. One was to blow tobacco smoke into the offending ear. Another was to spit tobacco juice into it. A third was to instill warm pickerel juice into the ear canal. This juice is obtained by skinning a pickerel and hanging it in the window where the sun can get at it. The heat of the sun melts the layer of fat along its back, the fat draining into a bottle under the suspended fish. This oil is warmed before using. A hot baked potato or the roasted heart of an onion held against the ear was also considered valuable.

Food for children too young to chew was chewed by some fond parent or relative and then given to the baby. This was known as "muming."

In some families, children always wore a string of Job's tears round their necks during the teething period, these round seeds of an East Indian grass being famed as preventives of fever at this troublesome time. In Alexandria five years ago I noticed a child wearing a white strap around his shoulders crossing in the front and back of his chest, in figure-of-eight fashion. His mother explained that this was a "teething jacket." That was the only time I ever happened to see one, but an Indiana colleague tells me that the practice is quite common in the Middle West.

Every time a child was ill, but especially if he ground his teeth at night, he was considered to be suffering from "worms"—unless proved otherwise. And often he would promptly receive a dose of beef gall. A tansy bag was hung around his neck to "prevent the worms from coming up into his throat and choking him to death." A much boasted treatment for tapeworm infestation was to starve the patient, and incidentally the worms, for three or four days. Then a bowl of steaming hot soup was held at the patient's mouth. The worms, getting the odor of food, would come up and could be caught. It is not clear to me

why this did not choke the patient to death. Punkinseed tea was also used for tapeworms.

SKIN TROUBLES, WARTS AND CHILBLAINS

Among the remedies for the various skin diseases were sulfur and rum for boils, gunpowder in water or the "sweet" from a heated axe for ringworm, Elder Hook's—he lived in Loudon—balm for "running sore," yellow dock boiled in vinegar for athlete's foot and balm of Gilead buds fried in mutton tallow for bedsores. Wounds from rusty nails, were and still are, bound snugly with a thick slice of salt pork, which allegedly "draws like a plaster." White pine pitch or human urine was used for cuts and wounds. For poisoning due to snakebite, snake root was frequently used. A squish poultice was "laid on" for the bite of the water moccasin, whereas the cut surface of an onion was applied for the bite of the rattlesnake. The fact that in time the cut surface turned black was ample proof that the poison had "come out." Butter and flour is still the quick relief for ordinary burns, but around Andover a "fresh cow dressing" was long used for surface burns.

Woodsmen in this region are reputed to have eaten the leaves of poison ivy in the spring of the year to prevent ivy poisoning. This practice was said to have no injurious effect on the mucous membranes of the mouth or gastrointestinal tract, yet to produce a seasonal immunity of the skin to the poison. For victims of this weed, selendine or sweet fern was rubbed on.

For warts, mystic incantations and general hocus pocus were apparently much more effective than herbs. Many of the methods have a familiar ring. "Rub the wart with a bean and throw the bean away, rub the wart with salt pork and bury the salt pork, rub the wart with a used dish cloth and hide the cloth, tie it around with a string and bury the string." There is a lady in Lakeport who, out of the goodness of her heart, will buy your wart. She gives you a penny, you bury the penny, and, "presto chango," the wart is gone. But one old timer said, "They warn't nawthin better fer warts 'n t' rub 'em with selendine." Mike Ackerman, of Alexandria, had a method all his own. "He didn't even need to see his patient. He had only to know that someone had a wart. He then simply went into some sort of consultation with a hobgoblin or a brownie or the devil or something, and shortly thereafter the wart was cured. He cured Will Price of his wart while Will was way down in Massachusetts in the Melrose Hospital and Mike himself was still in Alexandria. He also cured Will's nurse of her warts at the same time."

To ease chilblains, these people used to put their shoes under the bed "so's they point toward the rud." Or they rubbed their feet with kerosene or turpentine or pigs-foot oil, or painted on oil of spike (lavender) with a feather. Or they cut an onion, salted it and rubbed the cut surface on their feet. Or they walked barefoot on a cold painted floor or in the snow.

HERB DOCTORS

Usually one person in a community became especially adept at the preparation and prescription of these herbs, and became known around the countryside as a good "herb doctor"—like "Aunt" Samuel Crosby, of Hebron, "Aunt Head," of Sandwich, and half-Indian "Doctor Dodge," of Groton. Very often the herb doctor and midwife were combined in one person. Some even became very successful quacks and competed with regular practitioners of medicine. Such a one was Samuel Thomson, who was born in Alstead in 1769. The peregrinations of this "traveling" doctor included Alstead, Walpole, Surry, Portsmouth, Hillsborough, Royalton, Warwick, Salisbury Mills and Exeter in New Hampshire, Eastham, Newburyport and Salem in Massachusetts, Woodstock, Jericho and Georgia in Vermont, and Kittery and Eastport in Maine. In the last-named town he boasted that he drove three of the five regular physicians out of practice. He sold "rights," that is, memberships in his so-called "Friendly Botanic Society," to his system of treatment, which he patented in 1813. His aim was to raise the "inward heat above the outward" by the use of lobelia, which promoted free perspiration, and cayenne pepper (capsicum); to "cleanse" the stomach by giving an emetic; and, when necessary, to use a steam bath followed by a concoction of bayberry, sumac, hemlock bark, witch-hazel leaves, red-raspberry leaves and marsh rosemary, or any two or three of these, to "clear the canker." He "cured" cancers with pipsissewa, and was greatly annoyed at the ingratitude of "cured" patients and his constant persecution at the hands of the regular members of the profession.⁷ In 1809 he was accused of killing a patient with lobelia.

THE HERB PROJECT

There has recently been a revival of interest in the cultivation of medicinal herbs in New Hampshire. To help recoup the fast-dwindling agricultural income of the state the Department of Agriculture established in 1936 an herb nursery at Pembroke, aided by a WPA "Medicinal Herb Project," to the best of my knowledge, the only one of its kind in the country. This agency grows and distributes among small farmers seedlings of herbs suited to New Hampshire culture and finds a ready market for the cultivated herbs. This season 48,000 herb plants were distributed to seventy-two growers in forty-seven towns. For practical purposes the state herb nursery concentrates on ten herbs, advising new growers to limit themselves to these: catnip, digitalis, peppermint, sage, spearmint and pyrethrum (perennials), and summer savory, winter savory, sweet basil and sweet marjoram (annuals). The following medicinal herbs can also be cultivated with profit in New Hampshire: rosemary, stramonium (Jimson weed), thyme and valerian.⁸

* * *

One may be amused at the faith that these people placed in the healing virtues of their herbs, but it is nonetheless true that modern research has substantiated many of the old ideas. After all, it was from old English folklore that Withering culled the idea that digitalis was useful in dropsy. And it is not at all inconceivable that some of the remedies listed above may have a like rationale.

DEFICIENCY DISEASES: THEIR DIAGNOSIS AND TREATMENT*

CORNELIUS P. RHOADS, M.D.†

NEW YORK CITY

SCURVY as a clinical problem supposedly disappeared decades ago from general medical practice. Pellagra, as a fully developed symptom complex, is rare in northern latitudes. Isolated symptoms clinically, pathologically and therapeutically indistinguishable from those of pellagra may be found in any hospital ward. Beriberi, supposedly a disease of only rice-eating populations of tropical lands, may be seen regularly in any large community.

The extent to which information gained from study of obvious deficiency disease may be applied to the problems of clinical medicine has not been realized. Many symptom complexes of previously unknown etiology, such as pernicious anemia and sprue, are now included under the heading of deficiency disease, and there is a constant tendency so to include an ever-increasing number of pathologic conditions.

Purely laboratory investigations of the effects of inadequate diet have given diverse and often conflicting results. Such a mass of contradictory data has appeared that the application of the results of animal experimentation to the problems of disease in human beings is uncertain.

The purpose of this report is to present a simple outline of deficiency diseases as they are seen in man, and to discuss certain principles on which their successful recognition and treatment depend.

DEFINITION

As employed in this report, the term "primary deficiency disease" is applied to those marked conditions that follow an intake of certain dietary constituents inadequate to maintain health in normal persons. It is, however, most important to recognize that deficiency disease may occur despite a diet sufficient for the average person. This occurrence is due to an increased demand for the essential dietary substances or to certain factors which interfere with their delivery at the site of their utilization in the form in which they are utilized. Symptoms like those of primary deficiency disease which occur despite a diet adequate for normal persons are termed manifestations of "secondary deficiency disease."

RECOGNITION OF DEFICIENCY DISEASE

The recognition of the characteristic symptom complexes of dietary lack such as beriberi, pellagra and scurvy is relatively simple. The clinical pictures are striking, and the improvement which follows the administration of the proper dietary compounds is dramatic.

A more serious clinical problem concerns the recognition of disease manifestations as due to a deficiency when the familiar complete symptom complex is not present and the dietary lack is not obvious. For example, it is held that the stomatitis and atrophic glossitis of pellagra differ in no respect, either morphologically or in their response to therapy, from the stomatitis and glossitis which occur in certain patients without dermatitis, diarrhea and delirium; and the peripheral neuritis of beriberi in the Philippines is symptomatically and therapeutically similar to the peripheral neuritis of alcoholism which is encountered in Bellevue Hospital.

Clinical and experimental evidence make it clear that almost every system of the body may be affected by a lack of essential food constituents. The different manifestations may be present together in a complete symptom complex such as pellagra or pernicious anemia. In other cases only certain components of the complex may appear independently, such as glossitis, combined system disease or diarrhea. These individual symptoms appear to respond to specific dietary therapy quite as well as the complex as a whole.

It becomes apparent that the degree of deficiency and the susceptibility of the patient are such potent factors that the manifestations of dietary lack may be exceedingly varied and difficult of recognition. The diagnosis of individual symptoms that appear in the absence of a complete disease complex is suggested by the morphologic similarity of the lesions to those seen in classic deficiency disease, and is confirmed by the response to specific therapy.

CAUSATION OF DEFICIENCY DISEASE

Improper diet as the cause of primary deficiency disease has been recognized since the time of the Crusades, and the dramatic results of the specific therapy of scurvy, of pellagra and of beriberi are among the most striking of modern medicine

*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 15, 1940.

†Professor of pathology, Cornell University Medical College, director, Memorial Hospital.

Only recently has the more obscure secondary deficiency disease that occurs despite an adequate dietary intake been understood. It is with the varied manifestations of this condition that the clinician is concerned most frequently, and illustrative material can be obtained from a study of the disturbances of blood formation that result from a lack of certain food constituents.

This material can be employed because changes in hematopoiesis are sensitive indicators of effective therapy, and lend themselves to graphic representation. Neurologic changes, cutaneous alterations, lesions of the mucous membranes, disturbances of ocular function or even such a subjective factor as appetite could be employed, however, if quantitative methods for their estimation were available.

At least six different mechanisms are now known to exist by which secondary deficiency diseases may develop. These will be discussed in order.

The first is loss of essential dietary substances by diarrhea. Study of the symptomatology of the morbid states characterized by protracted diarrhea such as that accompanying ulcerative colitis, chronic dysentery and intestinal tuberculosis reveals that changes of the skin, of the mucous membranes and of the blood are frequently encountered (Mackie and Henriques¹). These changes are similar in all respects to the lesions of the same organs that are seen in deficiency disease due to obviously inadequate dietary intake. They are assumed to be caused by a simple loss of vitamins from the bowel, because they frequently disappear when the diarrhea is checked although other factors remain unchanged.

The second cause of secondary dietary deficiency is an interference with the absorption of essential food substances. This mechanism is seen particularly in conditions in which dysfunction of the intestinal tract has been a feature for a considerable period, as in sprue. As this disease progresses the hematologic response to orally administered therapeutic agents becomes progressively less, although the response to the same substances parenterally administered remains unchanged (Castle and his co-workers²).

The third cause is a failure of the body to convert dietary constituents into the form in which they may be utilized. Such a mechanism obtains, for example, in the secondary deficiency known as pernicious anemia. In this condition, as has been shown by Castle and his co-workers,³ there is failure by the stomach to secrete a ferment that is necessary to convert some dietary constituent similar in distribution to the water-soluble, heat-stable, vitamin B into the form that is required

for proper hematopoiesis. The result is precisely what would be expected if the dietary constituent to be converted in the intestine were withdrawn from the food, as shown by the experiments of Wills.⁴

The fourth mechanism is made operative by the inhibitory power of infection on the action exerted by the essential food constituents. This mechanism is seen very frequently in a mild form in infectious disease. One of the most striking effects may be evaluated quantitatively from the reticulocyte response in pernicious anemia (Smithburn and Zerfas⁵).

The fifth mechanism is a congenital requirement for an abnormally high intake of certain dietary factors. The extraordinary variability in the response of different persons to the same dietary lack has been a prominent feature of all deficiency disease. Only recently, however, has experimental proof been available. The work of Brown⁶ has shown beyond question that certain young rabbits are abnormal at birth and will inevitably die unless the diet is supplemented by large amounts of certain vitamins. When this is done the animals may be kept in perfect health, but if the unusually great intake of vitamins is discontinued, disease symptoms recur. It is inferred that similar individual variations of lesser degree are operative in the cause of deficiency states in human beings.

The sixth mechanism involves an increased demand for accessory food factors properly to detoxify certain poisonous compounds. As indicated by the evidence at hand, however, it appears that certain amounts of a toxic compound such as dimethylamidoazobenzol may be tolerated by a normal animal when fed a normal diet. If the content of the diet in certain vitamins (probably related to vitamin B) is decreased, symptoms promptly occur (Suguira and Rhoads⁷).

TREATMENT OF DEFICIENCY DISEASE

Certain fundamental principles are of the greatest importance in the treatment of the conditions under discussion, and unless these principles are observed the results are very frequently unsatisfactory. Four such principles will be here discussed.

The Threshold Requirement

In treating such conditions as pellagra and sprue, and at times pernicious anemia, clear evidence is at hand that a well-defined quantitative requirement for therapy exists. If less than the required amount is given, no response is obtained. Once the requirement is exceeded, however, even

if on only one occasion, a distinct effect can be detected.

Analysis of case records in which specific vitamin therapy is stated to have failed reveals that the commonest cause of failure is insufficient dosage. Because minute amounts of food constituents relieve experimental deficiency states in animals, it is assumed that similar amounts will be effective in man. This emphatically is not the case, and therapy must be pushed until the desired effect is produced.

The objection will be raised that overdosage of certain vitamins, for example, vitamin D, have been shown to be toxic to animals. This is undeniably true, but it is equally true that the margin between the therapeutic and the toxic dose is so great that it is doubtful whether overdosage of human beings can be effected except by intent.

Parenteral Administration of Therapeutic Agents

In view of the role of decreased absorption from the intestinal tract in the causation of deficiency disease, it is clear that treatment should be administered parenterally in case the oral route has given unsatisfactory results. Here again, pellagra, sprue and pernicious anemia afford striking proof. The studies of Castle and his co-workers⁸ in sprue have advanced unequivocal evidence that certain cases may be wholly refractory to oral treatment. Only by intensive parenteral treatment may satisfactory results be achieved.

Multiple Deficiency States

From the very nature of the manner in which deficiency disease develops, it is apparent that symptoms due to lack of only one specific food constituent must be rare. Dietary intake, if poor, is almost always low in several accessory factors, and if symptoms are due to vitamin loss rather than to insufficient intake, the same situation obtains. Successful treatment depends on supplying all the elements which are lacking. If, for example, a case of anemia due to lack of two substances such as liver extract and iron is treated by the administration of either substance alone, only a partial remission can be expected.

Use of Concentrated Vitamin Preparations

From experience it has been concluded that the use of highly concentrated and purified vitamin preparations is to be avoided. If the necessity of parenteral administration requires a concentrate, it should be supplemented by crude material given orally. Knowledge of the nature of vitamins and the effects of their lack is fragmentary, and only incomplete conclusions concerning human disease can be drawn from animal experimentation. The

preparation of concentrates invariably involves some loss of active material.

* * *

In conclusion, primary and secondary deficiency disease have been defined and their mode of production analyzed. Certain principles of treatment have been discussed. If the material here presented is effective in suggesting the possibility of deficiency disease as a cause of obscure symptoms encountered in clinical practice, I shall consider my report justified.

DISCUSSION

DR. SIMON STONE, Manchester: We all should be grateful to Dr. Rhoads for the excellent summary he has given us in the use of vitamins in medicine. We all use vitamins, and sometimes I wonder if we are not using too much of them. After hearing Dr. Rhoads's paper, I believe that perhaps I have not been using enough. I should like to emphasize again the need of using the entire complex, instead of a small part of it.

Dr. Rhoads did not say much about vitamin E. Probably that was for a definite purpose. Vitamin E has come into use in the last two years. Its discovery was made by Evans in 1922, and reported in *Science*. He found that in certain cases of sterility it could be supplied by the addition of certain foodstuffs to the diet. In 1927 he published a book which is probably a landmark in vitamin therapy called *The Anti-Sterility, Fat-Soluble Vitamin E*. It dealt with the sterility in rats that could be produced by depriving the animal of vitamin E and could be cured by the addition of it. Evans mentions paralysis of young rats, which developed after their mothers had been deprived of this vitamin. A year later he published another paper with Burr, dealing with paralysis in young rats suckled by mothers deprived of vitamin E. This work remained forgotten for a time, but within the last two or three years Evans has devoted himself to paralysis in animals, and also in human cases, in which vitamin E deficiency is considered to be one of the major causes. Within the past year, Wechsler published a paper dealing with the use of vitamin E, in animals and in human beings, for lateral sclerosis, in which vitamin E deficiency is considered to be one of the major causes.

In April, 1939, we began an investigation at the Balch Hospital on the use of vitamin E in muscular dystrophies. We have treated about 20 patients so far, and in about 10 of them have obtained excellent results. In the past, cases

with muscular dystrophy were considered to have a poor prognosis. Various diets have been given, as well as injections of aminoacids, thyroid adrenalins, without producing satisfactory results. Some of our patients who had considerable difficulty in getting around are now walking quite well. We have also noted definite changes in the musculature of these patients. Previously the muscles were fatty and flabby and had no tone; since then their condition has changed to normal.

There are other conditions in which vitamin D or B probably is important, such as tabes dorsalis and possibly some other types of muscular atrophy. We are investigating some of the uses of vitamin E in such conditions, through the assistance of the Venereal Control Department and the Crippled Children's Services.

I should appreciate it very much if Dr. Rhoads could tell us about the recent advances in the work with vitamin E.

DR. HAROLD D. LEVINE, Bristol: I should like to ask Dr. Rhoads if he can say anything about the significance of a coated tongue.

DR. EZRA A. JONES, Manchester: I should like to ask Dr. Rhoads if he is using vitamin D for delayed union in fractures.

DR. FRANK N. ROGERS, Manchester: In addition to the question on coated tongue, I should like to include one on the type of tongue known as the geographic tongue. Is that condition related to an avitaminosis? Also, should massive initial doses of vitamin D be given for the cure of rickets?

DR. RALPH W. HUNTER, Hanover: I should like to ask Dr. Rhoads if there are any toxic effects from overdoses of vitamin B. Also, does brewer's yeast contain all the factors of vitamin B?

A PHYSICIAN: I should like to ask Dr. Rhoads about the effectiveness of large doses of vitamin D in psoriasis.

DR. RHOADS: As to the question regarding vitamin E in lateral sclerosis: Of course, everyone was highly excited by Wechsler's contribution to this subject. I believe that the group at the New York Hospital have been pursuing the matter with some intensity, but I personally have not had any experience with it. I think that the work just mentioned here is one of the most clear-cut studies of which I have heard. Certainly, so far as New York is concerned, an insufficient number of cases have been treated to warrant any conclusion.

An answer to the question concerning coated tongue must be somewhat speculative, I think. In some cases, coated tongue represents a very early stage of acute glossitis. We have followed a number of cases of coated tongue through to the peeling off of the surface and the leaving behind of the red, beefy, atrophic epithelium; this suggests that at least one form is a manifestation of deficiency disease.

As to the use of vitamin D in nonunited fractures, no more can be done with this vitamin, so far as I know, than to make it possible for the patient to absorb calcium. The latter may be decreased by a variety of disorders of the intestinal tract, hence vitamin D is extraordinarily useful in treating secondary calcium deficiency by supporting the absorption of calcium. I have had no practical experience with the problem of ununited fractures, but from the experimental work, I am inclined to think that I should treat any cases of delayed union with

enough vitamin D to ensure proper absorption of calcium. But calcium must be given too. The giving of vitamin D will not result in the absorption of calcium that is not there.

Geographic tongue is a very interesting condition, but I do not know very much about it. People with pernicious anemia are likely to have it. I have been inclined to believe, with others, that it occurs in patients with the abnormal mucosa that may result in pernicious anemia, if the strain is severe enough. I do not believe that this condition, as ordinarily described, can be cured by the vitamin B complex. However, it is sometimes associated with atrophy of the tongue, which can be cured readily.

As to the use of vitamin D in rickets, one of my patients with this disease is now taking 200,000 units of vitamin D a day. He simply does not absorb it normally; hence he does not absorb calcium. In the classic studies, as high as 1,000,000 units a day has been given for a week to get proper calcium levels. As with all these vitamins, it must be given in sufficient quantities to obtain the desired effect. No rule for dosage can be laid down, because there are so many other factors involved. If one wishes to cure rickets, one must give enough vitamin D, as well as calcium and phosphorus, to obtain normal levels. Of course massive doses can be toxic, and the patient must be closely watched.

As to the toxic effects of vitamin B complex, I have had a certain number of patients complain of jitters and dizziness with heavy doses of vitamin B₁ (up to 100 mg. a day). I have known other physicians who have complained that their patients had similar symptoms. I do not believe that these are serious. Of course 100 mg. a day is a large dose, and in my experience it is given only rarely.

I know of no dose of riboflavin that is toxic. I have never given more than 20 mg. a day for two weeks, so that I am not in a position to judge its toxicity. I have given animals 500 mg. a day without toxic effect.

Nicotinic acid will, in many patients, give a distinctly toxic reaction in the form of flushing, palpitation and a feeling of pressure in the pit of the stomach. I do not know why it does not do this all the time. The irregular effect is a problem. I doubt if one needs to give the compound to the point of toxic symptoms. With continued heavy doses of nicotinic acid, certain patients lose weight and become quite sick. This is a danger which one must consider. There is an overdosage factor, beyond question, but I do not believe that it results in permanent damage.

As to brewer's yeast, I should say that its success depends on the way it is prepared. If it is oxidized by exposure to the air some constituents are lost. If it is boiled long enough, the vitamin B₁ element will of course be destroyed. Practically, brewer's yeast does contain all the factors described, provided it is a good quality of yeast and is properly prepared. This is true of Fleischmann's 2040, for example. It has a completely adequate supplement to basic diets in animals, and, so far as we know, it contains all the factors. I do not believe that all yeasts are of the same quality. The whole question is difficult, indeed, because yeast is hard to take. We are now trying to provide a yeast that can be taken and is effective. The evidence is clear that in yeast many factors are needed and cannot so far be obtained from a bottle sold by the drug houses.

As to psoriasis, I have not seen any striking cures brought about by vitamin D. I certainly am not satisfied that vitamin D is specific for psoriasis, but I am glad to accept the evidence as it appears. Physicians at the Mayo Clinic assure me that they have had dramatic cures of

psoriasis They give doses of vitamin D that ought to be toxic, but they say they are not. I should not dare give as much of it as they do. They say that they watch the blood calcium carefully, and have had cures in a large number of cases. I have not had enough personal experience to warrant any statement.

While I am on the subject of vitamin D, it might be worth while mentioning that the various reports that are appearing concerning the cure of arthritis by this vitamin are not substantiated, at least in my experience. I have never seen any case of arthritis cured by any vitamin.

HOW MAY THE GENERAL PRACTITIONER DIAGNOSE CANCER OF THE UTERUS?*

FRED L. ADAIR, M.D.†

CHICAGO

THERE are several reasons why the recognition and the treatment of cancer of the uterus are important. Cancer is one of the great killers of mankind. It occupies first rank, being second only to cardiovascular disease. It is very frequent in the breasts and uteri, women being particularly susceptible to this disease. When neglected by patient or doctor, cancer grows beyond control, and marches rapidly to irrevocable, intolerable suffering and death. If detected and properly treated early in its course, health and life may be prolonged, and the natural life span may be completed. It is important to realize that cancer is a curable condition, and that, as in other diseases, the percentage of favorable results obtained depends on early diagnosis and appropriate treatment.

We are here concerned with cancer of the uterus, which occurs in the age groups above twenty-five. It is of various cellular types, which occur with varying frequency at different sites. The usual sites are the vaginal portion, the endocervix and the corpus of the uterus. Some state that in 100 cases about 85 occur in the portion, 10 in the corpus, and 5 in the endocervix. Others believe that about 17 per cent of uterine cancer occurs in the corpus. My own relatively small series shows 50 per cent of uterine carcinoma in the corpus—an unusually high incidence. Primary carcinoma of the vagina is relatively uncommon, although it is frequently seen as an ultimate complication of carcinoma of the cervix.

It is often difficult to determine whether the primary site is in the upper part of the cervix or in the lower part of the corpus. One can classify

these cases only very early in the course of development. It is, therefore, often difficult to tell whether or not those cases occurring in the region of the isthmus uteri are primarily corpus or cervix carcinomas. It is much easier, of course, to differentiate cervix and corpus carcinoma when the site is in the region of the external os or low in the cervix, or in the corpus of the uterus at a level higher than the isthmus. Microscopically, some of these cases should be differentiated by the type of epithelium, although cases of squamous cell carcinoma have occurred in the endocervix and also in the corpus. It is fair to state that pure squamous cell carcinoma and adenocarcinoma with mucous secretion are usually cervical in origin. The differentiation of cases that develop primarily in the upper portion of the cervix or the lower portion of the corpus is not so important clinically, since they are usually of analogous types and behave similarly. In cervical carcinoma, the corpus of the uterus is usually not enlarged unless there is some stenosis of the cervical canal leading to the formation of a hemiometra or a pyometra, or unless there are some complicating neoplasms such as fibromyomas.

For many reasons it is important to reach some general agreement relative to the different stages of cancer of the cervix uteri. Unless some distinction is made and recognized between the different cases, it is impossible to evaluate the results of treatment and also to determine which is the best treatment for the different stages and types of carcinoma. The reports of the results of radiotherapy in cancer of the uterine cervix by the League of Nations College‡ in 1938 give certain definitions as approved in the year 1937. These

League of Nations Health Organization, *Ann. of Report on the Results of Radiotherapy in Cancer of the Uterine Cervix*, Vol. 3, Results Obtained in 1932 (Cited in 1938), 149 pp., London: Allen and Unwin, 1939.

are modified somewhat from those approved in 1929, and are as follows:

Stage I

The carcinoma is strictly confined to the cervix.

Stage II

The carcinoma infiltrates the parametrium on one or both sides, but has not invaded the pelvic wall: *Stage II, Parametrium*. The carcinoma infiltrates the vagina, but does not involve its lower third: *Stage II, Vagina*. Endocervical carcinoma, which has spread to the corpus: *Stage II, Corpus*.

Stage III

The carcinomatous infiltration of the parametrium has invaded the pelvic wall on one or both sides; on rectal examination, no cancer-free space is found between the tumor and the pelvic wall: *Stage III, Parametrium*. The carcinoma involves the lower third of the vagina: *Stage III, Vagina*. Isolated carcinomatous metastases are palpable on the pelvic wall (irrespective of the extent of the primary cervical growth): *Stage III, Isolated Pelvic Metastases*.

Stage IV

The carcinoma involves the bladder, as determined by cystoscopic examination or by the presence of a vesicovaginal fistula: *Stage IV, Bladder*. The carcinoma involves the rectum: *Stage IV, Rectum*. The carcinoma has spread outside the true pelvis (below the vaginal inlet, above the pelvic brim, distant metastases): *Stage IV, Distant Spread*.

The general rules to be observed according to this report are as follows:

When allocating a case to a stage nothing but facts revealed by examination should be taken into account. The stage of each case should be decided upon examination prior to treatment, and this classification should remain. The classification should be postponed quite exceptionally and the reasons stated. When it is doubtful to which stage a given case is to be allocated the earlier stage should be chosen. The fact that a single case presents two or more of the conditions which characterize a single stage does not affect this statement.

The summary of the report, which is the third of the series, includes statements from six radiotherapeutic centers. The data from these different centers have been combined and together furnish information concerning 9061 patients who suffered from cancer of the uterine cervix, of which 7958 or 87.8 per cent were treated by radiation therapy. Table 1 shows the results obtained after the lapse of five years of this treatment.

Various attempts have been made to grade, on the basis of microscopic examination, both carcinoma of the cervix and carcinoma of the corpus. This grading has not proved to be entirely satisfactory and is not of great interest to the ordinary practitioner of medicine. About 5 to 10 per cent

of the carcinomas of the cervix are of glandular, and the remainder are of the squamous-cell type. Practically all corpus carcinomas originate from the glandular epithelium. It must be borne in mind, however, that all cancers are not equally malignant.

No entirely satisfactory basis has yet been obtained by which one can prognosticate the ultimate outcome of a case of cancer. The most satisfactory basis for prognostication is the extent of the carcinoma when it is first seen. Not all types are equally amenable to treatment by radiation ther-

TABLE 1. *Results After Five Years of Radiation Therapy.*

apy. In general, it may be said that the less mature the cells and the less the degree of differentiation the more radiosensitive the cancer. Those that are more slowly growing, with the maturer type of cells, are more radioresistant.

Of approximately 75,000 women who die annually of cancer, about 16,000 may be expected to die of cancer of the uterus. Statistics show that of women who reach the age of thirty, about 1 in 37 may be expected to die of cancer of the uterus. This hazard increases until about the age of fifty, after which it declines with the increased age attained by the woman. The age decade in which the disease is most frequent is that from forty to forty-nine, although the group between fifty and fifty-nine is a close second. Carcinoma of the corpus occurs more frequently between fifty and sixty, whereas carcinoma of the cervix occurs oftener between forty and fifty. However, one should realize that any woman after the age of twenty-five is subject to carcinoma of the cervix and of the uterus.

The mere fact that a woman has not borne children does not exclude this possibility, since approximately 10 per cent of the carcinomas of the cervix occur in nulliparous women, which is not particularly disproportionate to the total number of women in this age group who have not been pregnant. It should also be recognized that complicating conditions do not exclude carcinoma of the uterus. Carcinoma occurring during pregnancy is not particularly common, but apparently occurs about once in 7000 or 8000 pregnant women. Also, fibromyomas of the uterus do not exclude the possibility of a carcinoma either of the cervix or of the corpus. I have found about 2 per cent of

uteri with fibromyomas in which there was a complicating carcinoma. Thirty-eight per cent of cases of carcinoma of the corpus have fibroids. Furthermore, one must remember that when an incomplete hysterectomy has been performed, the cervix is liable to become the site of a carcinoma. It not infrequently happens that a carcinoma of the cervix may exist at the time of the removal of the corpus of the uterus and may be discovered subsequently. In the diagnosis of carcinoma of the uterus, therefore, it is important to bear in mind that these conditions mentioned above do not exclude the possibility of a carcinoma either of the cervix or of the corpus of the uterus. Precautions should be taken to make a diagnosis, particularly when an operation is to be performed for some plastic or other procedure, and especially in those cases in which the decision has to be reached relative to removal or retention of the uterus. In 1 per cent of the cases of incomplete hysterectomy, carcinoma of the stump is discovered subsequently. Statistics show that the increased mortality in total hysterectomy over incomplete hysterectomy does not warrant the former, in view of the low incidence of carcinoma of the stump. The five-year survival of carcinoma of the stump is 14 per cent, and of the cervix 22 per cent.

The diagnosis of carcinoma of the uterus is made on the basis of the history and the physical examination, but for a diagnosis the patient must report to the physician. Consequently, it is part of the physician's duty to his patients and community to stress the fact that any unusual symptoms associated with or originating from the uterus, such as irregular or profuse bleeding,—no matter in what period of life,—should be investigated and the cause determined.

The most significant symptom to which the patient's attention should be directed is any abnormal genital bleeding. This may consist in interval bleeding, profuse menstruation, prolonged menstruation, a short interval between menstrual periods, contact bleeding or recurrence of bleeding following the menopause. It seems to be a frequent impression among the laity, and not an uncommon one among physicians, that disturbances of menstruation or recurrence of the menstrual flow following its cessation in the menopausal period are symptoms that may be anticipated as a part of the normal climacterium. This is not a safe basis on which to stand, either for the patient or for the physician, and any case of postmenopausal bleeding should be studied carefully to determine whether or not there are any organic changes, particularly those associated with

the development of early cancer. It is, therefore, the early diagnosis that one should stress. In the early diagnosis, palpatory findings, bimanual examination and speculum examination are of the utmost importance. I have frequently seen women who have reported previously to physicians and have not been examined, with the result that cancer has been overlooked for the time being. Therefore, the first essential that should be kept in mind by the practicing physician is that any such woman seeking medical advice must have a physical examination, including examination both with the fingers and with the speculum. Admitting that it requires considerable experience to detect early lesions and to be certain that they are cancerous, it is ordinarily not very difficult to detect a suspicious lesion on the cervix, when the case should be referred to someone who is more experienced than the practitioner for diagnosis, or a biopsy should be made and the tissue subjected to microscopic examination.

What conditions on a cervix may confuse the diagnosis of early carcinoma? The commonest lesion is erosion, with or without laceration of the cervix. Another is a polyp or papillary growth. The so-called "Nabothian cysts" are not ordinarily confused with a carcinomatous nodule. Small ulcers on the cervix also occur, sometimes in association with and sometimes independent of cervical erosion. The patient may report that she noticed a slight blood stain following intercourse or the taking of a douche. Such a patient should be carefully examined. One may find on the cervix a small lesion that bleeds easily on contact. If a polyp is present, it should be removed and subjected to microscopic examination. Malignant polyps are relatively rare; however, one not infrequently finds a cervical polyp associated with a carcinoma of the corpus, and in such cases the bleeding may be thought to be due to the former whereas it arises in the latter. Bleeding papillary growths and noncystic nodules should be removed for microscopic examination.

The so-called "Schiller test"—the application of an aqueous solution containing 0.3 per cent iodine and 0.7 per cent potassium iodide—may reveal a suspicious area. If an unstained area shows with this test, there is always a possibility of a cancer. The Schiller test depends on a quality of the squamous epithelium for absorbing iodine and taking a mahogany stain, whereas a cancerous area may remain unstained. The greater the experience of the observer, the more valuable a special test, such as this, becomes. It should not, however, be falsely interpreted. Nonmalignant as well as malignant lesions fail to stain with iodine, owing

to the absence of glycogen. The Hinselmann colposcope gives one an enlarged picture of this area, which has to be interpreted by the observer as the lesion would when observed with the naked eye. Neither of these procedures enables one to make a positive diagnosis of cancer. They merely point out suspicious areas.

In obtaining biopsy specimens the practitioner should be careful to secure an adequate piece of tissue, including the suspicious area or a portion of it, and also including some normal tissue on either side of the suspicious area if it is not too large to be thus excised. The early stages often present difficulties from the standpoint of both gross and microscopic diagnosis. It is, therefore, important that the microscopist know exactly the source of the tissue and have a specimen adequate for examination. There are many confusing pictures in tissue removed from the cervix, and one who is expert should make the microscopic diagnosis. Accuracy depends not on the microscope, but on the skill and ability of the one making the diagnosis.

The recognition of lesions of the endocervix and of the corpus of the uterus is more difficult, because these areas cannot be visualized. The symptoms are about the same, and consist in abnormal bleeding. Contact bleeding is less common from lesions in the endocervix and in the body of the uterus. Interval bleeding is common in both, but perhaps more so in lesions of the endocervix. Corporeal lesions are more inclined to produce profuse or prolonged menstruation, or recurrence of the menstrual epoch following the cessation of menstruation. Early in the course of carcinoma these lesions of the corpus and of the endocervix produce few, if any, gross physical findings.

When an endocervical lesion is suspected from the history, a probe or cotton applicator passed into the cervical canal will reveal some roughness, possibly excavation or possibly stenosis or contact bleeding. If such evidence is found, it may be necessary to secure a biopsy specimen with a sharp curette introduced into the cervical canal, by which sufficient tissue for microscopic examination can be secured. The palpatory findings may be significant by revealing an area of peculiar hardness, except in cases of papillary carcinoma, when the growth is unusually friable. In some cases a fine probe passed into a suspicious area produces a parchmentlike resistance.

Malignant lesions of the corpus are even more obscure, and produce no visual and practically no palpatory findings in their early course. There is virtually no asymmetry or enlargement of the uterus in the early stage. These occur only after

the process has advanced to a considerable degree. The only means of making an early diagnosis is by the use of diagnostic dilatation and curettage, which should be resorted to quite freely in suspicious cases. In my series of cases curetted for suspicious corporeal bleeding, there was microscopic evidence of carcinoma in approximately 16 per cent, and approximately 4 per cent of these were without any evidence of cancer on physical examination. In moderately advanced cases, of course, there is enlargement or asymmetry of the uterus, and in cases that are still more advanced there may be some fixation and spread to the surrounding tissue, with evidence of induration and lymphatic involvement. One should strive for early rather than for late diagnosis.

The recognition of late or advanced cancer presents little difficulty. The pain, discharge and bleeding are more or less characteristic. Physical examination may reveal definite physical findings in and about the cervix of the uterus that make the diagnosis relatively easy to determine. Other conditions that come under consideration are the granulomatous lesions due to syphilis, tuberculosis or other venereal diseases. Relatively speaking, the importance of diagnosis of late uterine cancer is of little significance because the outlook for cure is bad, and although some of the unpleasant symptoms may be eliminated and life somewhat prolonged, the possibility of cure is relatively remote.

The symptom of pain in cases of late carcinoma has unfavorable prognostic significance. Also symptoms referable to neighboring structures, such as the bladder and rectum, occur in advanced rather than early cases. Cachexia, which used to be stressed as a diagnostic sign, is largely a misnomer; it is in no way peculiar to cancer, but is the result of blood loss, infection and interference with the nutritive processes and other important functions of the body.

The treatment varies with the site, type and stage. Practically all agree at the present time that radiation therapy is the preferential form of treatment for carcinoma of the uterus. Whether or not this should be supplemented by surgery depends on the stage of the case when it is first recognized, and on the services available for radiation therapy and surgical methods. Two types of surgical procedure may be used: first, radical treatment, which includes the extensive removal of all actually and potentially involved parts; secondly, adjuvant treatment, which supplements radiation therapy by procuring better radium application or by removing involved structures that are not accessible or susceptible to radiation therapy. These questions usually have to be settled by the

expert in the management of carcinoma of the uterus. However, the practitioner should be conversant with some of the methods to be used, and should advise the patient accordingly, after making the diagnosis.

A protest should be voiced against the indiscriminate employment of radium and deep x-ray therapy by those who are not versed in their use. Improperly used these agents become either ineffective or dangerous or both. Their value depends

on their proper use and not on the radioactive agent itself.

The general practitioner is often the first to be consulted in cases of uterine cancer. He should make a diagnosis and see that appropriate treatment is instituted without delay. Every week lost in making a diagnosis and in instituting treatment reduces life expectancy and lessens the chances of cure.

HERPES ZOSTER: LOCAL ANESTHESIA IN THE TREATMENT OF PAIN

LAZARUS SECUNDA, M.D.,* WILLIAM WOLF, M.D.,† AND JERRY C. PRICE, M.D.‡

BOSTON

HERPES zoster is a disease of unknown etiology that may occur alone or in combination with a wide variety of diseases of the spinal cord or posterior root ganglia. The disease is characterized by severe pain in the distribution of one or more nerve roots and the appearance of tense vesicles on a highly inflammatory base in the area innervated by these roots.

Evaluation of the treatment of herpes zoster is extremely difficult on account of the variations in the severity and duration of the pain, and the site and destructiveness of the local lesions. In children the disease is usually mild, and sequelae are rare; in older people, however, relatively minor skin lesions may be accompanied by severe, excruciating neuralgic pains that persist for many months or years after the skin lesions have disappeared.

The present-day treatment of herpes zoster consists in local therapy to the skin lesions, medication for the relief of pain, and medical or physical therapy directed toward a cure of the inflammatory process in the posterior root ganglia. Treatment of the local lesions with dressings or poultices should be avoided, since they are apt to increase the incidence of secondary infection. A simple calamine lotion or a dry antiseptic dusting powder is useful. The results with local anesthetic ointments are in general disappointing.

Specific therapy of the inflammatory process in the posterior root ganglia has not yielded any striking results. Among the therapeutic agents that have been tried are posterior pituitary extract (Sidlick¹ and Niles²), x-rays (Vignal,³ Keich-

line⁴ and Pillsbury and Fondé⁵), sodium iodide (Ruggles⁶ and Pillsbury and Fondé⁷), sulfapyridine (Sutton and Sutton⁸), foreign-protein, and ultraviolet or infrared light. Although many of the above methods of therapy were used with the hope of relieving pain, the rationale behind most of them was to produce an amelioration of the inflammatory process in the posterior ganglia.

Treatment of the pain of herpes zoster has usually been with drugs of the coaltar series, morphine and codeine have been avoided because of the danger of addiction. Rosenak⁹ reported relief from pain and regression of the vesicles after intravertebral and paravertebral injections of 0.5 per cent aqueous procaine solution, and Hollander⁹ in 1938 showed that an oil-soluble anesthetic could be injected subcutaneously in the hyperalgesic areas with prompt relief of the pain, without recurrence when the anesthesia wore off four weeks later.

It is the purpose of this article to report the results of the treatment of 15 unselected cases of herpes zoster by the method of Hollander.

MATERIAL AND TECHNIC

Most of the patients received injections of 0.5 to 2.0 per cent novocain, with or without adrenalin. Three preparations of anesthetic oil were used: Nupercain (Ciba), Hollander's formula and the following modification of Hollander's formula:

Benzocaine	3
Benzyl alcohol	10
Phenol	1
Oil of sweet almond	q s ad 100

The areas of hyperesthesia were mapped out by the usual methods (pinprick, brush or pinching). These areas were cleansed with 95 per cent al-

*House officer, Department of Neurology, Boston City Hospital

†Assistant, Department of Dermatology, Boston City Hospital

‡Research fellow, Department of Neurology, Harvard Medical School, research associate in neurology, Boston City Hospital

cohol, and infiltrated subcutaneously with the therapeutic agent until there was total anesthesia. The smallest-gauge needle possible (novocain, 25; oil, 21 to 22) was introduced at the periphery of the predetermined area of hyperesthesia, and small quantities of the anesthetic agent were deposited in the tissues in a fan-shaped manner to underlay the entire hyperalgesic area. When vesicular, papular or pustular lesions were present, the anesthesia agent was injected immediately under the inflammatory tissue. The criterion for successful injection was complete loss of all cutaneous sensation in the injected areas. The absence of nerve block was indicated by the fact that anesthesia was confined to the area injected. Care was taken to see that the oil did not pool in small areas by massaging lightly after the injection was made.

RESULTS

Results were considered satisfactory when the anesthesia produced by the injection was accompanied by complete relief of the pain. Local therapeutic measures were avoided except for the protection from infection. The usual duration of anesthesia from novocain was from one to two hours, and that from the oil solution about one week.

Fourteen patients were injected with novocain, with complete relief of pain immediately after the injection in 13 (Table 1). The duration of this relief varied from one to thirty or more hours,

had been complete relief of the pain from the novocain injection, and in the remaining 2 further treatment was refused. There was complete relief of the pain in 7 of the 9 patients injected with the oil anesthetic. One patient (Case 14) was entirely free of pain for six months but later developed postherpetic neuralgia, and another (Case 15) suffered an increase in the pain after the injection and developed postherpetic neuralgia. Local reactions to the injection of the anesthetic oil were soreness, redness, swelling and pain at the site of the injection. Two patients experienced mild chilly sensations, and there was a possible febrile reaction in 1 (the temperature was not recorded). The duration of these side reactions varied from a few to forty-eight hours, and they were controlled by local applications of heat or analgesics by mouth. No accumulation of oil or abscesses occurred. In 2 patients there was a local infiltration at the site of the injection for as long as three weeks.

The results on the whole, were encouraging. Relief from the acute attack was experienced by 13 of the 15 patients treated. Ten of 13 patients followed for a period of six to twenty-one months were permanently relieved of all discomfort. There were 3 failures, 1 with novocain and 2 with a combination of the two anesthetic agents. In the first patient (Case 13) the injection of the novocain produced an increase in the pain, and in the second (Case 15) injection of the anesthetic

14	65	Intercostal	60	2 hours	6 months	12	Postherpetic neuralgia
15	60	Intercostal	21	5 hours	0 (worse)	3	Postherpetic neuralgia

*Patient did not return for further observation.

after which pain recurred with equal or greater severity in all but 4 patients. Reactions to novocain were limited to slight local soreness and tenderness on pressure. In one patient (Case 13), the pain was made worse by the injection of novocain.

Eight of the 14 patients injected with novocain and one other (Case 5) were subsequently treated by injection of the anesthetic oil. Four patients did not receive the latter treatment because there

oil produced an exacerbation of the pain, although temporary relief from the pain had been obtained previously with an injection of novocain. A satisfactory response to both anesthetics was noted in the third patient (Case 14), but complete relief of all discomfort for a period of six months was followed by a classic postherpetic neuralgia.

The clinical course of the skin lesions was not affected. Regression of the vesicles occurred in

the expected seven to fourteen days.⁷ Postherpetic neuralgia occurred only in patients of the older age group (sixty to sixty-five years). Two cases (not included in this series) of classic postherpetic neuralgia failed to respond to this method of treatment.

Although relief of the pain was the main object of these injections, it was gratifying to note that loss of the pain was accompanied by amelioration of muscular disabilities, improved appetite, normal sleep and ability to return to work in several patients.

SUMMARY

Local anesthesia produced by subcutaneous infiltration of the hyperalgesic areas with novocain or oil soluble anesthetics produced a relief from the pain in 13 of 15 patients with acute herpes zoster. The duration of the relief after the injection of novocain was usually from one to thirty

hours, following which there was a recurrence of the pain. Seven of the 9 patients receiving the combination of novocain and oil solution experienced permanent relief of the pain.

The clinical course of the skin lesion was not altered.

Postherpetic neuralgia developed in 3 patients

A STUDY OF VITAMIN C NUTRITION IN A GROUP OF SCHOOL CHILDREN

Clinical and Laboratory Studies*

MARIAN M CRANE, M.D.,† AND PHILIP W WOODS, DDS‡

WASHINGTON, D C, AND AUGUSTA, MAINE

THE observation of clinical evidence of vitamin C deficiency in a number of children in Maine during 1937 and 1938 aroused the concern of the director of the State Bureau of Health about the prevalence of vitamin C deficiency in the State. Studies of the foods produced and marketed in various parts of Maine had also suggested to the head of the Department of Biology of the Maine Agricultural Experiment Station the desirability of obtaining information concerning the food habits and the state of vitamin C nutrition of the population.

This study was undertaken to determine the state of vitamin C nutrition of a group of children attending an elementary school in a Maine village. Most of the children in this school were of French-Canadian extraction, and it should be pointed out that the results of the survey are applicable only to this one group.

*From the Children's Bureau, United States Department of Labor, Washington, D C, and the Bureau of Health, State Department of Health and Welfare, Augusta, Maine.

†Specialist in clinical hygiene, Children's Bureau, United States Department of Labor, Washington, D C.

‡Division director, State Bureau of Health, Division of Dental Health, Augusta, Maine.

MATERIAL AND METHODS OF STUDY§

Eighty six children were studied in the autumn of 1938 and again in the spring of 1939. These children were unselected except for age and sex, so that there is no known reason why the state of nutrition of the group should be expected to differ from that of the population of 700 in the school as a whole. The group included 39 boys and 47 girls, ranging in age from seven to sixteen years. In general there were a few more girls than boys in each age group.

Physical examinations were made during the autumn survey. With the exception of the mouth conditions to be discussed later, no physical signs of vitamin C deficiency were recognized. Because of the difficulties involved in attempting to assess

§The authors express their appreciation to Miss Mary M. Clayton of the Maine Agricultural Experiment Station for advice and assistance with respect to technical methods; to Miss Elizabeth F. Murphy of the same station for assistance in the interpretation of dietary findings; to Miss Elizabeth M. Waters, nutrition consultant in the Division of Maternal and Child Health of the State Bureau of Health for the collection of data relative to the diets of the children; and to the personnel of the school in which the study was made and to the local representatives of the State Bureau of Health without whose wholehearted cooperation the study would not have been possible.

the general nutritional status and to correlate it with specific findings, the physical examinations were not repeated in the spring.

In the autumn and again in the spring the study of the 86 children included examination of the blood to determine the level of ascorbic acid in the plasma and examination of the gums by a dentist for clinical evidence of vitamin C deficiency. Furthermore, tests of tolerance to a dose of ascorbic acid were made on the urines of 49 children, and the therapeutic value of vitamin C in improving inflammatory conditions of the gums was tested in 41 children.

In interpreting the data obtained, caution is necessary because of the incomplete state of present knowledge as to the metabolism of vitamin C and the exact significance of specific values for vitamin C in blood plasma or urine, and also because of the limitations inherent in the analysis of a relatively small sample.

RESULTS OF STUDY

Examination of the Blood

Determination of the plasma-ascorbic acid values was by titration of macroscopic samples of plasma with indophenol.* Under the conditions of the present study, it was impracticable to make the determinations on fasting subjects, but the children were questioned regarding the foods eaten

TABLE 1. Values of Ascorbic Acid in the Blood Plasma of 86 Children Examined Both in the Autumn and in the Spring.

that day; only 7 of the 86 children in the autumn and 16 in the spring had eaten citrus fruit or tomato on the day of the test. For these children it is possible that the plasma-ascorbic acid values obtained may indicate a state of vitamin C nutrition superior to that which actually existed.

The results of the autumn and spring determinations of plasma ascorbic acid are shown in Table 1. The lower limit for values indicating satisfactory vitamin C nutrition has generally been considered to be in the neighborhood of 0.80 mg. per 100 cc.¹⁻⁶ The majority of the children studied — 73 (85 per cent) in the autumn and 75 (87 per

cent) in the spring — had values below this level.

Plasma-ascorbic acid levels below 0.40 mg. per 100 cc. have usually been found to be associated with vitamin C undernutrition.^{1, 2-5} Most of the values obtained were in this relatively low range; 39 children (46 per cent) in the autumn and 54 (63 per cent) in the spring had values below 0.40 mg. per 100 cc. The total number of children who had relatively low values (less than 0.40 mg.) was considerably greater in the spring than in the autumn, whereas the number who had intermediate values (between 0.40 and 0.79 mg.) was smaller in the spring.

Because certain investigators believe that clinical manifestation of scurvy may occur in the presence of plasma-ascorbic acid values of 0.15 mg. per 100 cc. or less,^{1, 4} it is worthy of note that the 10 chil-

Totals	86	54	21	4	7

dren who had values below 0.20 mg. in the autumn, and the 20 children who had values in this range in the spring, actually had values of 0.15 mg. or less, yet none of them showed the classic signs of the disease.

Table 2 shows the association between the values obtained in the autumn and those obtained in the spring. It is possible to see from this table the extent to which the children maintained relatively constant levels of ascorbic acid in the blood, or showed a rise or a fall in ascorbic acid values.

Of the 39 children who in the autumn had low plasma-ascorbic acid values (below 0.40 mg. per 100 cc.), 24 still had values within this range in the spring, and 15 had higher values (10 between 0.40 and 0.79 mg., 1 between 0.80 and 1.19 mg., and 4 of 1.20 mg. or more). Of the 34 children who in the autumn had intermediate values (between 0.40 and 0.79 mg.), 23 had dropped into the low group by spring, 7 remained at the same general level, and only 4 had values that fell into higher groups.

Twenty-four children, or 28 per cent of the entire group, had low values (below 0.40 mg. per 100 cc.) for ascorbic acid in both autumn and spring. In addition, 23 children, or 27 per cent, had intermediate values (between 0.40 and 0.79 mg.) in the autumn that dropped into the low group by spring. Therefore, 55 per cent of the 86 children had either

*The technic used was that published by Ingalls,⁷ with slight modifications by Miss Mary M. Clayton, of the Maine Agricultural Experiment Station. Potassium cyanide was used in some of the first determinations made in the autumn but was omitted in all later determinations.

relatively low values at both examinations or slightly higher values in the autumn that had dropped to relatively low values by spring.

Only 2 of the 86 children had ascorbic acid values of 0.80 mg. per 100 cc. or higher at both autumn and spring examinations.

In the light of present knowledge of their significance, these values may be summarized as follows: Approximately 55 per cent of the 86 children had values of ascorbic acid in the blood plasma that are usually associated with vitamin C undernutrition—nearly 28 per cent were in the relatively low group in both autumn and spring, and about 27 per cent, who were in the intermediate group in autumn, had dropped into the low group in spring. Only 2 of the 86 children had plasma-ascorbic acid values both in autumn and in spring that indicated satisfactory vitamin C nutrition.

Tests for Vitamin C Tolerance

To check the evidence obtained from the plasma-ascorbic acid tests against another method for estimating vitamin C nutrition, tests of tolerance to a test dose of ascorbic acid were made on the urine.

Both urinary tolerance tests and plasma-ascorbic acid tests were made on each of 49 children—23 were from the group of 86 unselected children previously described, and 26 were others from the school selected because of specific mouth findings—to determine to what degree the tolerance test would confirm the evidence given by the plasma-ascorbic acid values concerning the state of vitamin C nutrition of the group.

The procedure used in the urinary tolerance test was as follows:

Urine was collected with special precautions for preservation of vitamin C during a control period of six hours on the first day, and the amount of ascorbic acid contained in the specimen was determined by titration with indophenol immediately at the close of the period. Plasma ascorbic acid was determined on the same day. The ascorbic acid excretion during a similar six-hour period was determined on the second day, but at the beginning of the period of collection the child was given 400 mg. of crystalline ascorbic acid by mouth. The excess excretion of ascorbic acid during the second period as compared with the first was considered to be the amount of the test dose that was excreted in the six hours following administration.

The results of these tests on the 49 children are shown in Table 3. Examination of the table shows that the 28 children who had plasma-ascorbic acid values of less than 0.40 mg. per 100 cc. excreted relatively small proportions of the test dose. Twenty-four excreted less than 2 per cent of the dose, and the other 4 excreted less than 10 per cent. In contrast, the 4 children with plasma levels of 0.80 mg. per 100 cc. or above excreted more than 10 per cent of the test dose, in some

cases more than 30 per cent. Without attempting to attach clinical significance to the excretion of any specific amounts of the test dose, it is apparent that the results of the urinary tolerance test tend to

confirm the evidence obtained from the plasma-ascorbic acid values as to the state of vitamin C nutrition of this group of children.

Examination of the Mouths

The mouths of the 86 children were examined by one of us (P. W. W.) in both autumn and spring. Examination did not reveal the markedly swollen, spongy or bleeding gums that are generally recognized as typical signs of frank scurvy, but a milder degree of inflammation of the gums was frequently observed.

Inflammation of the oral mucosa was observed most frequently on the labial aspect of the upper jaw, less frequently on the buccal aspects of the maxillas and the labial aspect of the mandible, and least frequently on the lingual and palatal aspects.

To stabilize the recording of oral inflammation and to make possible the detection of changes in the manifestation of the inflammatory reactions, standards for recording the extent of the inflammation were set up, and the inflammation was classified as slight, moderate or extensive.* When, as

*The cardinal signs of inflammation as manifested in the mouth were the determining factors in classifying the findings. Erythema was the commonest sign, and edema as manifested by swelling and a spongy feeling was nearly as frequent. The tumor of edema was distinguished from the firm swelling characteristic of hypertrophy and of hyperplasia. Questioning a child for pain proved to be unimportant. No attempt was made to rate color. The first symptom of oral inflammation along with one or more of the points mentioned above, was the loss of the normal supple on the surface of the epithelium, manifested by a smooth glossy appearance, with distinct high lights reflected.

If the inflammation was limited to the interdental papillae in the embrasures so that triangular regions of inflamed tissues were seen to be isolated from the affected tissue of an adjacent embrasure, the extent of inflammation was regarded as slight. The islands of oral inflammation presented themselves in the interdental papillae in any locality of the mouth.

If the inflammation progressed from the interdental papillae into the continuous mucous membrane covering the alveoli, so that the evidences of the reaction were found not only in the embrasure but also in the tissues of the crest of the ridge, it was regarded as moderate. In other words, the reaction had in these cases extended from the interdental papillae up into the mucous membrane covering the alveolar ridges so that the swollen tissues became contingent over the necks of the teeth. When the edematous tissues measured approximately 2 mm in the direction of the long axis of the tooth, the limit of the moderate reaction was reached.

If the inflammation extended from the alveoli beyond the limits set up into the moderate reaction so that the greater portion of the gum tissue was involved and the gums presented a marked inflammatory aspect, it was regarded as extensive.

Although this procedure was developed independently, it has many points of similarity with that of Hinkle.¹

often happened, the extent of the inflammation varied in different parts of the same mouth, the greatest extent present was chosen as the basis for

TABLE 4. *Condition of Gums of 86 Children Examined Both in the Autumn and in the Spring.*

according to the presence or absence of inflammation of the gums and the extent of inflammation.

At the time of the autumn examination, slightly more than one third of the children had inflam-

tum and 12 in the spring — had inflammation of moderate degree, and about 5 per cent (4 children) had extensive inflammation.

A comparison of the extent of inflammation noted in the 86 children in the autumn with that observed in the same children in the spring is shown in Table 5. Thirty-five (41 per cent) of the children were free from inflammation at both examinations. Twenty-five (29 per cent) who had inflamed gums in the autumn also had inflamed gums in the spring. In addition, 19 children (22 per cent) who had healthy gums in the autumn had developed inflammation by spring. Altogether, therefore, a total of 44 children, slightly more than half of the group, had inflamed gums at the time of the spring examination.

If vitamin C deficiency is a cause of the inflammation of the gums observed in these children, one would expect that inflammation would be found more frequently in children with low plasma-ascorbic acid values than in those with higher values. The comparison of the distribution of plasma-ascorbic acid values with the distribution of inflammation of the gums would be more satisfactory if it had been possible to make the examinations of the mouths in the autumn nearer the time of the blood examinations than was done in some cases. In the spring the two examinations in all cases were made within, at most, seven days of each other, but in the autumn in many cases there was an interval of fourteen to twenty-seven days (in a few cases twenty-eight to thirty days) between the two examinations, so that it is possible that the state of vitamin C nutrition of some of the children may have changed in the interval.

mation of the gums of some degree; in the spring about half had such inflammation. The extent of the inflammation was most frequently slight; slight inflammation was observed in 17, or 20 per cent, of the children in the autumn and was even commoner in the spring, when it was noted in 28, or 33 per cent. In both the autumn and the spring 13 or 14 per cent — 11 children in the au-

There is, nevertheless, evidence of an association between the presence of inflammation of the gums and low plasma-ascorbic acid levels.

In Table 6 the children are classified in four groups: those who had low plasma-ascorbic acid values (below 0.40 mg. per 100 cc.) in both the autumn and spring; those who had values of 0.40 mg. or above in the autumn but low values in the

spring; those who had low values in the autumn but high values in the spring; and those who had values of 0.40 mg. or above at both examinations. For each of these groups are shown the number of children who had inflammation of the gums at both examinations, the number who had inflammation in the spring but not in autumn, the number who had inflammation in the autumn but not in spring, and the number who were free from inflammation at both examinations.

If an association exists between the level of ascorbic acid in the plasma and the presence or absence of inflammation of the gums, this should be best demonstrated by a comparison of the frequency with which inflammation was observed to be present or absent at both examinations in the two groups that offer the sharpest contrast in terms of plasma-ascorbic acid levels, namely, the 24 children who had low values in both autumn and spring, and the 17 children who had high values at both examinations. These groups are small, but they are fairly clear-cut in terms of plasma-ascorbic acid values. Of the 24 children with consistently low ascorbic acid values in both the autumn and spring, only 3 children were free from inflammation of the gums at both examinations; of the 17 children with consistently high ascorbic acid values, 10, or 59 per cent, were entirely free from inflammation. Inflammation was observed both in autumn and in spring in 11, or nearly half, of the children with low ascorbic acid values, and in only 3, or not quite one sixth, of those with high values.

Effect of Vitamin C Therapy on Inflammation of the Gums

To obtain further evidence of the apparent association between vitamin C undernutrition and inflammation of the gums, a therapeutic test with

TABLE 7. *Extent of Inflammation of the Gums before and after Vitamin C Therapy Given to 41 Children.*

EXTENT OF INFLAMMATION BEFORE THERAPY	NO. OF CASES	EXTENT OF INFLAMMATION AFTER THERAPY			
		NONE	SLIGHT	MODERATE	EXTENSIVE
Slight	16	8	8	—	—
Moderate	19	5	12	2	—
Extensive	6	—	2	1	3
Totals	41	13	22	3	3

vitamin C was given in the spring to 41 children who showed such inflammation. Twenty-six were from the group of 86 examined in both the autumn and the spring who could best be depended on to co-operate in the test, and 15 were other children who had inflamed gums. Table 7 shows the association between the mouth findings before and after therapy. Six children showed ex-

tensive, 19 moderate and 16 slight inflammation at the beginning of the test. Each child was supplied with tablets containing 50 mg. of crystalline ascorbic acid, with instructions to take 4 tablets daily. Between nineteen and twenty-one days after the therapy was started, the mouths were re-examined. Twenty-eight, or about two thirds, of the 41 children showed improvement in the condition of the gums, and 13 of these were free from inflammation. In 13, or about one third of the children, the extent of the inflammation was unchanged after therapy. No child showed an increase in the extent of the inflammation.

Since inflammation of the gums was observed more frequently in children with consistently low plasma-ascorbic acid values than in those with consistently high values, and since improvement in the extent of the inflammation was observed within only three weeks in approximately two thirds of the 41 children who were given vitamin C therapy, it may be concluded that vitamin C undernutrition is in all probability an important factor in the causation of this type of inflammation.

The observation of inflammation of the gums in 44, or slightly more than half the children, examined in both the autumn and spring (the 25 who had inflammation of the gums at both examinations and the additional 19 who had developed inflammation by spring) suggests that there was a high incidence of vitamin C undernutrition in the group.

Evaluation of Diets

Information obtained concerning the diets of a number of children in the school (76 in the autumn, 63 in the spring) showed that during both autumn and spring very few of the children ate foods that are sources of vitamin C frequently enough to provide an adequate intake of the vitamin. A good source of vitamin C* was eaten with an average frequency of once daily by not more than one child in seven at either season. At least half the children (43 of 76 in the autumn, and 32 of 63 in the spring) did not eat even a fair source of the vitamin, other than potato, oftener than once a day, and about one sixth (14 in the autumn, and 10 in the spring) did not eat such a food more than twice during the week for which diet records were kept. A detailed study of the diets and of the vitamin C content of the foods commonly used is to be published separately.⁸

COMMENTS

It is recognized that there are certain limitations in the information regarding vitamin C nutrition

*Foods considered good sources of vitamin C were citrus fruits, tomato, cabbage and turnip (rutabaga).

that can be obtained from a single determination of plasma-ascorbic acid value. The level of ascorbic acid in the blood is apparently influenced much more rapidly by variations in the vitamin C intake than the stores of the vitamin in the tissues are. The error from this source is probably less, however, in the study of a group than in the study of the individual, since in a group there is the possibility that a variation from the usual diet in one subject will be counterbalanced by a variation in the opposite direction in another subject. In the present study the results have been further stabilized by basing the conclusions on two determinations of plasma ascorbic acid on each child, with a considerable time interval between the determinations.

The comparison of the results of the urinary tolerance test with the results of the determination of the plasma-ascorbic acid level indicates that, although there may be a few cases in which the results of the two tests give somewhat contradictory evidence of the state of vitamin C nutrition, the general picture presented for a group of children is much the same in both tests.

The possibility has been pointed out that for some of the children the plasma-ascorbic acid values obtained may have been influenced by foods containing vitamin C that were eaten on the day of the test. In the spring it is also possible that some of the children had had an unusual amount of citrus fruit in their diets during the few days immediately preceding their tests, because the Federal Surplus Commodities Corporation had distributed grapefruit to the families of about half the 86 children two days after the time at which the examinations were started. In either event the results obtained from the tests would be unduly high and would result in underestimation rather than overestimation of the prevalence of vitamin C undernutrition in this group of children.

The comparison of plasma-ascorbic acid values with mouth findings has shown that inflammation of the gums was present more frequently in children who had consistently low levels of ascorbic acid in the plasma than in those who had higher levels. It is to be expected that there would be cases in which inflammation of the gums was present and the plasma-ascorbic acid level was not low, and conversely, cases with low plasma-ascorbic acid values and no inflammation, since the inflammation, if due to vitamin C deficiency, is probably the result of a long-continued deficiency, whereas the plasma-ascorbic acid value may be temporarily higher or lower than the usual level as a result of recent variations from the ordinary diet. Individual exceptions, therefore, do not detract from the evidence of an association between

inflammation of the gums and low plasma-ascorbic acid values. This evidence is materially strengthened by the improvement in the condition of the gums observed in two thirds of the children given a therapeutic test over a short period. Although deficiency of vitamin C appears to be an important causative factor in the production of inflammation of the gums of the type observed, there is no evidence that it is the only factor. It may well be that other conditions, such as poor mouth hygiene and other types of nutritional deficiency, also play a part in the production.

Since it was found in the autumn and again in the spring that about 55 per cent of 86 children had plasma-ascorbic acid values that are usually associated with vitamin C undernutrition, and that inflammation of the gums, probably due in part at least to vitamin C deficiency, was noted in about 51 per cent (both in autumn and in spring in approximately 29 per cent of the children and in the spring alone in an additional group of about 22 per cent), it appears that a considerable number of the children in this group were vitamin C deficient during that part of the year when relatively few home-grown fruits and vegetables are available. That many more of these children were probably on the borderline of inadequate vitamin C nutrition is indicated by the finding that only 2 had plasma-ascorbic acid values at both examinations that are considered to indicate adequate vitamin C intake, and that at neither examination did more than about 15 per cent of the children have such values. These findings do not, of course, give any information of the vitamin C level during those months of the year when home-grown fruits and vegetables are relatively plentiful.

The frequent finding of inflammation of the gums in these children and the evidence that this inflammation is associated with vitamin C undernutrition seem to indicate that for many of the children in the group there had been a deficiency in vitamin C intake sufficient to cause recognizable impairment of physical well-being.

SUMMARY

A study of the status with respect to vitamin C nutrition of a group of 86 children chiefly of French-Canadian extraction, attending an elementary school in a Maine village, was made during those months of the year when relatively few home-grown fruits and vegetables are available. The results of this study indicate that a considerable number of these children were undernourished with respect to vitamin C, as is shown by the following findings.

Examination of the blood showed that of the 86 children, 55 per cent had relatively low values

(less than 0.40 mg. per 100 cc.) for vitamin C in the blood plasma. Twenty-eight per cent had low values both in autumn and in spring, and 27 per cent had slightly higher values (0.40 to 0.79 mg.) in the autumn but low values in the spring. Such low values have usually been found to be associated with vitamin C undernutrition. Only 2 of the children had values that were high enough both in autumn and in spring to be considered evidence of adequate vitamin C intake (0.80 mg. or above). A comparison of plasma-ascorbic acid values with the results of urinary tests for vitamin C tolerance in 49 children lends support to the reliability of plasma ascorbic acid values as an indication of the state of vitamin C nutrition.

Examination of the mouths of the same 86 children showed that the 29 per cent who had some degree of inflammation of the gums in the autumn also had some degree of inflammation in the spring, and about 51 per cent (an additional 22 per cent) had inflamed gums in the spring. This

inflammation was found to be more frequent in children with consistently low values (less than 0.40 mg. per 100 cc.) for plasma ascorbic acid than in those with consistently high values, and the condition was observed to improve in approximately two thirds of 41 children with inflamed gums who were given vitamin C therapy for three weeks. Vitamin C deficiency, therefore, appeared to be a factor in the production of the inflammation of the gums observed in these children.

MEDICAL PROGRESS

TREATMENT OF BILIARY-TRACT DISEASE

CHESTER M. JONES, M.D.*

BOSTON

SUCCESSFUL treatment of biliary tract disease resolves itself essentially into an attempt to safeguard known physiologic functions or to replace such functions as have been lost or temporarily disturbed. Except for strictly surgical procedures directed at the removal or drainage of focal infection in the biliary tract, such physiologic considerations are of primary therapeutic importance and form the basis of successful surgical, as well as medical, maneuvers. The treatment of serious intrahepatic disease is by no means the forlorn hope that it was formerly thought to be. A reasonable optimism is becoming increasingly evident in the treatment of hepatic disorders, owing to the knowledge that more or less specific remedial measures exist that if properly applied may at least restore a fair degree of function, even if a complete cure is not possible. The regenerative powers of the liver are well known, and it is essential to recognize the reason for such optimism, which is based on the more recent knowledge available concerning measures designed to supplement or replace many of the multiple functions

of this organ. It is also important to differentiate measures that are strictly protective against damage to the liver and those that are effective in aiding repair once damage has been produced by one or another noxious agent.

Avoidance of specific toxins still constitutes a fundamental approach to the problem of liver disease, and reference may justifiably be made to various reports of liver damage due to substances encountered in the routine treatment of other diseases or to industrial hazards. In spite of its well known toxicity, chloroform continues to be a source of hepatic damage. An interesting article is that by Townsend,¹ who reports 2 cases of acute yellow atrophy following the administration of chloroform in pregnancy. Of particular importance is the fact that in each case the toxic effects of the anesthetic were in all probability enhanced by starvation and dehydration secondary to prolonged vomiting, prior to the administration of the drug. The untoward effect on the liver of a too-enthusiastic use of the barbiturates is not generally recognized, and an article by Scheffely and Higgins² properly directs attention to the toxic

*Clinical professor of medicine, Harvard Medical School; physician, Massachusetts General Hospital.

effect of these drugs in the presence of liver damage. These authors studied the effect of several preparations used as hypnotics or as anesthetics in the presence of partially hepatectomized animals, and their findings strongly suggest that the intact liver is necessary in protecting against the action of pentobarbital sodium (Nembutal) and ethyl-o-ethylphenylurea. These and similar findings may well explain many of the unpleasant and sometimes serious disturbances occurring after the use of excessive amounts of such preparations in depleted patients or in patients suffering from biliary-tract disease.

A renewal of interest in the use of acacia as a means of maintaining normal plasma osmotic pressure relations makes it important to call attention to recent experimental work with this material. Among other articles, one by Hall, Gibson and Weed³ shows that the intravenous administration of gum acacia in dogs resulted in evident interference with the carbohydrate and serum-protein functions of the liver as evidenced by changes in the tolerance curves of glucose and galactose and by a fall in the plasma fibrinogen content. The bleeding time was prolonged, and it was noted that blood clots were small and fragile. Such findings confirm the observations of previous investigators that gum acacia may cause serious damage to the parenchymal cells of the liver and that its therapeutic use warrants careful scrutiny. The use of thorium dioxide in diagnosis has been subjected to criticism for some time. The report of Jacobson and Rosenbaum⁴ of a case in which the liver was examined five years after injection of the drug demonstrates its probable deleterious effects on the liver. Further confirmation is found in a study by Pohle and Ritchie,⁵ who examined microscopically the livers of dogs killed two years after the injection of Thorotrast. X-ray films taken at intervals during the period of observation showed no appreciable loss of density of the liver and spleen, and histologically there was hydropic degeneration of the liver cells. The findings were less in degree than those noted by other observers in rabbit experiments, but the authors properly considered the use of thorium for visualization of the liver and spleen in human beings to be definitely restricted to those cases in which the ultimate outcome is problematical.

The widespread use of sulfonamide preparations warrants a discussion of the possible toxic effect of such drugs on the liver. Van Winkle and Cutting⁶ in experiments in cats have demonstrated that the acetylation of sulfanilamide takes place fundamentally in the liver and spleen. Sulfapyridine is also acetylated in large part by the liver.

In the hepatectomized rabbit the acetylation of sulfanilamide does not occur. The finding of a direct van den Bergh reaction in certain cases of jaundice following the use of sulfanilamide seems to indicate direct damage to the liver.⁷ Although certain authors like Schmidt⁸ consider that sulfanilamide is not a hepatic poison, continued reports by most observers⁹⁻¹⁵ seem to produce incontrovertible evidence that the use of this drug can at times cause serious and even fatal liver disease. The unfortunate failure to consider seriously the dangers inherent in the prolonged and uncontrolled administration of sulfanilamide or Neoprontosil is evident in Russell's¹⁶ report of a case of acute toxic necrosis of the liver in which fatal liver damage occurred during prolonged treatment of a gonorrheal infection. Inasmuch as gonorrhea rarely if ever produces important hepatic changes, the unfortunate results obtained in this case may probably be laid to chemotherapy. It is obvious from these and similar reports that a continued recognition of the dangers inherent in the administration of sulfonamide compounds is warranted. Of this group, sulfanilamide to date seems to be the most dangerous in potential damage to the liver.

The occurrence of jaundice during antisyphilitic treatment constitutes a well-known complication of the modern therapy of this disease, although a real doubt still exists in the minds of many physicians concerning the hepatotoxic effects of the arsenicals. An excellent critical review of this subject is presented by Rankin and Marlow,¹⁷ who studied in great detail a series of 62 patients, in all of whom jaundice developed during the course of antisyphilitic treatment with arsenic. The authors conclude that subclinical residual liver damage appears to be present after recovery from postarsphenamine jaundice. In itself postarsphenamine hepatitis is not indicative of a poor prognosis. Alcoholic addiction or the continuation of arsenical therapy in the presence of otherwise static liver damage secondary to the use of the drug is probably hazardous. In certain cases, even after the disappearance of jaundice, it is of interest that the authors demonstrated an increased bilirubin retention and an apparent increase in the size of the liver in association with further arsenical treatment. The statement that patients recovering from "arsenical jaundice" should not use alcohol is confirmed by many examples in my experience and is a point that has not been sufficiently recognized. The article is critically written and is well worth reading. Further proof that postarsphenamine jaundice is an important entity is to be found in an article by Hanger and

Gutman.¹⁸ In most of the 92 patients studied the jaundice appeared to be of the hepatogenous type, as indicated by such laboratory studies as the determination of serum phosphatase, cephalin flocculation and cholesterol esters. The unusual findings indicative of an obstructive type of jaundice with a high phosphatase, normal flocculation and a normal hippuric acid excretion were observed in 12 cases. Proof of the obstructive nature of the disturbance in 4 patients was obtained by punch biopsies of the liver; the lesion in each consisted of inflammatory changes in the finer biliary radicals and bile thrombi in the terminal ducts, without marked changes in the liver parenchyma. Recovery occurred in these 12 patients, but there can be little doubt that these studies indicate a hitherto unsuspected type of hepatic damage caused by arsenic. Further evidence of the occasional dangers of antisyphilitic therapy can be found in the report by Wolman¹⁹ of 2 cases of acute hepatic necrosis in infants following the use of sodium bismuth thioglycollate. The author rightly condemns indiscriminate antisyphilitic treatment of infants born of syphilitic mothers. In each of the above fatal cases such treatment was carried out before signs of congenital disease had become evident.

The direct toxic effect of alcohol on the liver in the absence of other conditioning factors remains a controversial question. In my mind there is little doubt that clinically alcohol causes a serious disturbance of liver function and in all probability organic damage to the hepatic parenchyma in the presence of already existing disease of infectious or toxic origin. In the absence of pre-existing liver disease, there is still doubt of the exact effect of alcohol on the hepatic cell. For this reason an article by Newman et al.²⁰ is of distinct interest. These authors compare the effects of various glycols with that of ethyl alcohol, and show that the latter was metabolized directly by the liver and exerted a depressing effect on its functional activity as indicated by a decrease in oxygen consumption, an increase in blood lactic acid and a decrease in liver glycogen of as much as 45 per cent. Incidentally, it appeared that propylene glycol was the least injurious and objectionable of several glycols used as solvents. It is of interest to note that the addition of insulin to propylene glycol appeared definitely to decrease the oxygen consumption in the liver, and probably to diminish optimal hepatic activity. Connor's²¹ pathological study of so-called "alcoholic cirrhosis" should be mentioned. He reviews in detail studies of livers obtained from 47 chronic alcoholic patients, and presents a clear macroscopic and microscopic picture of the two important

phases of alcoholic cirrhosis: that associated with marked fatty enlargement of the organ with hyaline degeneration and atrophy of the peripheral cells associated with early fibrosis, and the later stage characterized particularly by proliferation of connective tissue and the typical picture of portal cirrhosis. Regardless of the fact that other factors, such as deficiency in specific food substances, undoubtedly condition the production of hepatic changes noted in chronic alcoholic patients, the importance of the effect of alcohol on the liver under certain conditions cannot reasonably be underestimated.

Cinchophen continues to contribute cases of fatal liver injury in spite of the fairly voluminous literature regarding its dangers. The cases reported by MacBryde²² constitute a warning that is still timely.

The use in industry of various solvents continues to add to the knowledge of poisons that may cause severe liver injury. A case of subacute yellow atrophy following exposure to a petroleum distillate known as "Stoddard's solvent," similar to benzene, is presented by Braunstein.²³ The case is important because of the infrequency with which petroleum products appear as causes of liver disorders. A potential hazard may also be mentioned, namely, that suggested by a recent editorial²⁴ on dangers associated with the operation of submarines. Arsine or arseniuretted hydrogen has long been known as a means of producing experimental liver injury. This gas is highly toxic in animals and in human beings, and may under certain conditions be present in submarines.

A fairly common cause of liver damage frequently escapes consideration from this particular angle, namely, the hepatic damage following severe burns. Serious burns are usually and properly considered in relation to the associated loss of fluids, electrolytes and plasma proteins. Structural changes may occur in the liver following burns, as noted in the report by Belt,²⁵ who compares the lesions to those observed in virus diseases such as yellow fever. There was widespread midzonal necrosis. The degree of cytoplasmic degeneration noted would amply explain the various changes, found by Wolff and his collaborators,²⁶ on bilirubinemia, bromsulfalein retention, hippuric acid formation, plasmaphrothrombin changes and dextrose-tolerance modifications seen in 3 patients. Whether these hepatic changes are due to a toxin derived from the burned area, anoxia associated with local capillary stasis, or infection cannot be stated; but it is obvious that the usual measures for treating acute liver insufficiency are indicated once the loss of plasma

protein and electrolytes has been adjusted. Such measures are of even greater importance when one considers that the restoration of plasma-protein deficits is extremely inadequate in the presence of liver failure.

To those readers interested in experimental production of liver damage by unusual agents, the reports on animal experiments on the use of such widely unrelated substances as the seeds of yellow burweed,²⁷ wheat from seleniferous soil,²⁸ dibenzanthracene²⁹ and butter-yellow³⁰ (*p*-dimethylaminoazobenzene) may be recommended. Of particular significance is the finding that the striking cirrhotic changes produced in rats by the use of butter-yellow were entirely reversible on withdrawal of the poison, even after the material had been administered for as long as eight months. Such restoration of hepatic parenchymatous changes to normal after prolonged intoxication provides adequate evidence of the importance of maintaining an optimistic attitude even in the treatment of chronic liver disease.

The importance of dietary measures in the treatment of liver disease is fairly well recognized, but such measures are not yet universally practiced. Experimental and clinical observations have long shown that an adequate supply of easily utilizable carbohydrates is essential for the protection of the liver against various toxins and probably for a restoration of normal hepatic function in the face of existing liver injury. Soskin and Hyman³¹ summarize the rationale of intensive dextrose therapy in diseases of the liver, particularly after damage has occurred from various toxic agents. The mechanism by which benefit is derived from intensive glucose therapy is still not thoroughly understood, but the fact that many toxic substances are excreted as glucuronates suggests that excessive stores of carbohydrates favor detoxification. An important point made by these authors is that the routine use of insulin in connection with dextrose therapy should be avoided unless the patient also has diabetes. In view of recent articles favoring the use of insulin in association with the treatment of acute hepatic damage, it is important to consider that this drug may defeat the very purpose for which dextrose is administered. The suggestion that insulin is contraindicated under such circumstances is also found in the article already referred to by Newman and his collaborators,²⁰ who show that the addition of insulin to propylene glycol inhibits normal hepatic-cell function, and by the even more important studies of Stadie, Lukens, and Zapp³² on the effect of insulin on liver metabolism. The recent studies of Miller and Whipple,³³ Ravdin^{34, 35} and others indicate clearly that an adequate protein intake is important for

proper regeneration following liver injury and for protection against potential liver toxins. That an adequate supply of carbohydrates is also essential and in some cases is of even greater importance is suggested by the studies of Bollman, Butt and Snell.³⁶ These authors caused extensive hepatic damage in rats by the use of carbon tetrachloride. The extensive hepatic necrosis appeared greatest in animals on a low-protein diet and least in those on a high-carbohydrate diet, whereas *regenerative* changes were more marked in animals on a high-protein intake. No correlation could be demonstrated between the amount of hepatic necrosis and the amount of prothrombin in the blood, but it is important to note that animals on high-carbohydrate diets survived without hemorrhage about half again as long as animals on either high-protein or high-fat diets.

The importance of an adequate protein intake in protecting the liver against damage has been well demonstrated by Ravdin and his collaborators.^{34, 35} These investigators showed that the damage from chloroform is independent of the glycogen content of the liver cells, increases progressively with an increase in concentration of hepatic lipids and is minimal when chloroform anesthesia has been preceded by a high-protein diet. They also showed that in the presence of experimental common-duct obstruction a diet high in protein and carbohydrate and containing no fat was found most effective in reducing the fatty-acid concentration of the liver and in increasing hepatic glycogen. This diet gave approximately the same result as the usual high-carbohydrate diet but in half the time. Miller and Whipple³³ likewise showed that protein depletion followed by chloroform anesthesia produced serious hepatic damage, whereas four to five times as much of the anesthetic could be tolerated with but little liver injury in the absence of protein deficiency. Mesinger and Hawkins³⁷ demonstrated that dogs were protected from hepatic damage by arsphenamine if fed an adequate protein diet. They stated that repair occurred more promptly on such a diet than on any other regime. A high-carbohydrate diet was not so uniformly protective. They also stressed the important fact that in animals protected from the toxic effects of arsphenamine by a high-protein or high-carbohydrate diet there was a progressive increase in the icteric index when the diet was changed to one high in fat, even though no additional arsphenamine was added. When fat-fed dogs, showing severe intoxication, were changed to high-protein or high-carbohydrate diets, they immediately recovered from the intoxicated state, and the icteric index decreased. These observations are entirely in keeping with my experi-

ences in the treatment of arsphenamine jaundice and other forms of acute or subacute liver injury. For practical purposes, however, the use of high-protein diets offers real difficulties when applied to patients with serious acute hepatic insufficiency. These patients are frequently incapable of eating anything but the simplest foods, and are often incapable of receiving an adequate intake by mouth. Under such circumstances, in the presence of existing serious liver damage, the immediate therapeutic indication is for adequate intravenous glucose therapy, supplemented by whole-blood or plasma transfusions. When it becomes possible to administer specific proteins intravenously, a very important contribution will have been made to our therapeutic armamentarium. On the other hand, in cases in which potential liver damage is present, such as in the course of antisyphilitic treatment, or in cases in which liver damage is of only moderate degree, there can be little doubt that the emphasis placed by Whipple, Ravdin and others on the importance of an adequate protein intake is of the utmost consequence from the point of view of probable protection against further damage, regeneration of hepatic cells, possibly more adequate gluconeogenesis and a better maintenance of plasma-protein relations. At the present time, liver and milk (casein) seem to be the most valuable forms of protein that are available.

When damage to liver cells has been checked and recovery is well under way, provided the original cause of hepatic disturbance has been removed, it is highly probable that the addition of fat to the diet in reasonable amounts is indicated. This is suggested by the observations of Machella, Higgins and Mann,³⁸ who showed that in partially hepatectomized animals the apparently greater degree of hepatic restoration under forced feeding was to a certain extent due to an accumulation of fat in the hepatic cells. Crandall, Ivy and Ehni³⁹ also suggested, as a result of their studies on hepatic acetone-body production during fasting and fat feeding, that ketogenesis may be a mechanism for supplying the tissues with substances that can be used to replace partially the role of glucose in conserving carbohydrate reserve and decreasing the need for gluconeogenesis. In other words, for protection against liver damage a diet high in protein and carbohydrate and extremely low or lacking in fat is indicated. For aiding the liver in recovery from existing damage a diet that is very high in carbohydrate and as high as possible in protein should be chosen. Once the original cause of the trouble has been removed and recovery is fully under way, a high-calorie diet including reasonable amounts of fat may

provide optimal conditions for maximum recovery.

Further convincing evidence of the importance of an adequate diet as a protection against liver damage has been presented by various investigators. György and Goldblatt⁴⁰ report the occurrence of widespread hepatic necrosis in rats kept on a diet lacking in vitamin B₂ or some other part of the B complex contained in yeast, and vonGlahn and Flinn⁴¹ found definite evidence of protection against arsenical liver injury by the addition of brewer's yeast to the diet. The latter noted that the amount of hepatic glycogen bore no relation to the degree of liver damage produced by arsenic, a finding also noted in Ravdin's experiments. Rich and Hamilton⁴² observed the development of cirrhosis of the liver in all of 14 rabbits kept on diets supplemented by various vitamins but lacking yeast. It is of interest that ascites occurred in 7 of the animals and also that microscopic, formed gallstones were found in intrahepatic bile ducts in several. These authors conclude that the lack of some factor exclusive of vitamins B₁, B₂, and B₆ and nicotinic acid, but contained in yeast, was responsible for the development of the hepatic lesions. The findings of Lauber and Bersin⁴³ contributed similar information concerning the protection afforded the liver by certain specific vitamins. During ether anesthesia the content of liver glycogen in the rabbit was noted to fall to 50 per cent of the preanesthetic level. When vitamin B₁ was administered several days previous to anesthesia, there was only a 10 to 15 per cent reduction in hepatic glycogen; and similarly, when vitamin A or vitamin D in adequate doses was administered for three days prior to ether narcosis, there was only a 15 to 20 per cent glycogen loss. The administration of vitamins B₂ and C did not influence the loss of glycogen from the liver cells.

Vitamin A deficiency has been noted by various observers in the presence of chronic liver disease, and obviously substitution therapy in replacing vitamin A lack in patients with cirrhosis and other chronic forms of hepatic disorders is indicated. Under these circumstances the administration of vitamin A is primarily aimed at correcting the symptoms of a specific vitamin insufficiency rather than protecting the liver from damage. Such a vitamin A lack may be due either to faulty absorption because of the relative lack of bile acids entering the small intestine or to an inadequate dietary intake, and is entirely comparable to similar deficiencies in other fat-soluble vitamins commonly observed in the course of hepatic disturbances. It is possible that a similar lack of vitamin D absorption in the presence of an inadequate intake or delivery of bile salts into the duodenum

may underlie the occasional incidence of pronounced osteoporosis and calcium deficiency observed in chronically jaundiced persons.^{44, 45} Under such circumstances it is obvious that the intensive use of bile acids in addition to an adequate intake of vitamin D and calcium is essential to correct the underlying osseous disturbance.

The obvious importance of a proper understanding of the relation between deficiency in another fat-soluble vitamin, vitamin K, and hepatic function is clearly shown in the numerous articles that have appeared on this subject in the last five years. Although vitamin K lack may occur in any condition in which profound nutritional disease exists, its particular interest lies in its effect on prothrombin deficiency and the tendency to spontaneous bleeding commonly observed in patients suffering from serious disease of the liver. Although in most cases such a condition can be corrected by the administration of adequate amounts of vitamin K, it is of the utmost consequence to remember that serious intrahepatic disease itself may interfere with adequate utilization of this vitamin and the subsequent restoration of prothrombin to normal. An inadequate response to vitamin K therapy in itself indicates liver damage of the most serious degree, and in the occasional case when the administration of vitamin K is ineffective it should be remembered that multiple frequent transfusions may still temporarily control an otherwise fatal bleeding tendency. The role of the liver in the utilization of vitamin K is borne out by numerous articles, experimental and clinical.⁴⁶⁻⁴⁹ That there may be a variable response to vitamin K therapy in a given person is suggested by the report of Ferguson and Calder.⁵⁰ These authors noted that in a patient suffering from a complete biliary fistula of four years' duration, in spite of the administration of constantly increasing amounts of a vitamin K preparation and bile salts by mouth, there were marked variations in the plasma prothrombin, the Ivy bleeding time and the serum-volume index. Although there was a marked initial rise in prothrombin following five days of intensive therapy, thereafter there was an abrupt fall in spite of intensive treatment. Normal figures were not obtained until surgical anastomosis had been performed between the common duct and the duodenum. Postoperative bleeding probably was avoided by the use of multiple transfusions immediately before and after surgical intervention. In this and similar cases of prolonged biliary fistula it is quite probable that disturbances in blood coagulation are due not only to a lack of absorption of vitamin K but also to the loss of valuable constituents on

the drainage bile. It is also possible that in this type of case the parenteral use of synthetic vitamin K (2-methyl-1,4-naphthoquinone) is the only desirable method of administration. For practical purposes it is highly probable that correction of hypoprothrombinemia will in the future be obtained most satisfactorily by such parenteral medication.⁵¹⁻⁵³ Finally, it is important to point out that as a precautionary measure the administration of vitamin K may be a proper preoperative procedure in any form of biliary-tract surgery in which prolonged vomiting or other cause of malnutrition has been present, even if there is no existing demonstrable disease of the liver or diversion of bile from the intestinal tract.

Attempts to affect choleresis by dietary measures or by the use of bile-salt preparations continue to attract attention. The oral administration of oleic acid was noted to stimulate the flow of bile, and the combination of bile salts and oleic acid produced a choleric effect beyond the additive effects of each of these stimulative agents.⁵⁴ The administration of olive oil, however, produced no such effect. A series of careful investigations on choleresis and the composition of bile has been carried out by Berman, Ivy and their collaborators⁵⁵⁻⁵⁸ on bile fistulas in dogs. Bile salts containing no cholesterol, when administered orally or intravenously, increase the cholesterol content of the bile. Further experiments were carried out using three types of bile-acid preparations: unoxidized, conjugated bile acids, as represented by the salts of glycholic and taurocholic acids found naturally in ox bile (Bilron, Fel Bovis); oxidized, conjugated bile acids, as represented by Dech-acid; and oxidized, unconjugated bile acids, as represented by Ketochol and Kebilac, which contain a mixture of mono-, di- and tri-ketocholanic acids, chiefly the last, and by Decholin, which is practically pure tri-ketocholanic acid or dehydrocholic acid. The conclusions drawn by these investigators are convincing and important. They believe that, if one desires to flush the bile ducts with "thin" bile, the use of one of the oxidized, unconjugated preparations of dehydrocholic acid or ketocholanic acid is indicated. If it is desired to increase the output of the bile of the liver and at the same time to increase its concentration in those bile salts naturally predominating in human bile, the use of a preparation of "natural" bile salts is to be advocated. The authors point out the very important fact that the presence of bile pigment in the feces does not necessarily indicate that bile salts are being excreted in the bile. The liver may excrete pigment when it does not form and excrete bile salts. Bile salts

can be used with the hope of counteracting a tendency toward stasis, but, to obtain a maximum effect, the patient must have a liver that will excrete bile salts. The authors are skeptical of the value of bile salt therapy in the presence of hepatitis or during recovery from obstruction, except for the purpose of improving intestinal absorption. Of some additional interest is their finding that intensive bile salt therapy over long periods produces no evidence of liver or kidney damage. It is known that this treatment increases the secretion pressure of bile, and therefore the intraductal pressure. Best, Hicken and Finlayson⁶⁹ make the important point that the continued use of bile salts results in a sharp rise in intraductal pressure, followed not infrequently by a drop to a level rather close to normal. If, therefore, the administration of bile salts is to be considered as a therapeutic measure to effect the expulsion of calculi from the common duct, optimum changes in intraductal pressure can be obtained only by the intensive use of bile salt preparations over short periods.

The etiology of infectious jaundice (so called "catarrhal jaundice") is still undetermined. Increasing evidence is appearing that in all probability this common condition is due to a filterable virus. Findlay's observations⁶⁰⁻⁶¹ in this regard are extremely interesting. This author remarks that on more than one occasion laboratory workers have contracted the disease when working with the serums of infected persons. During the course of yellow fever immunizations over a period of two years, 96 cases of jaundice occurred two to three months after inoculation, and in a fatal case subacute necrosis of the liver was found. Convincing proof was obtained that the jaundice was not due to the virus of yellow fever. The first proof that postinoculation jaundice could give rise to infectious jaundice was obtained following the use of pooled convalescent measles serum. In one institution 7 children became jaundiced ten to twelve weeks after inoculation, and 3 died of acute liver necrosis. Two months later 2 contacts who had not been inoculated developed infectious hepatitis. In 1937 McNulty⁶² reported that about 100 persons had developed infectious jaundice from this batch of pooled serum. Other similar experiences have been reported. Observation seems to indicate that the disease is spread by a droplet infection and has an incubation period of one month or more and an infectious period of one to ten days through the preicteric stage and three to five days in addition after the appearance of jaundice. In Denmark it has been suggested that it is identical with porcine hepatitis and may have been reproduced in human beings by the ingestion of in-

fected pork. In this respect the report by Andersen and Tulinus⁶³ is of interest. In one case, porcine hepatitis was induced by feeding a pig with duodenal juice obtained from a patient with acute epidemic jaundice. A second animal was similarly infected by feeding the liver from a pig with acute jaundice. Examination of the livers in the two infected animals showed that the lesions were identical. Somewhat different conclusions concerning the mode of spread of infection are contained in an article by Norton,⁶⁴ who reports 23 cases occurring in a rather isolated mining community. The sanitation of the community was unsatisfactory; the only milk supply was from an unclean dairy selling raw milk. It was believed that the infection was spread by intimate contact, and possibly through the food or water supply. Satisfactory control was obtained by the application of measures similar to those used in the control of typhoid fever. The average incubation time was apparently thirty-one days. Weil's disease was excluded by appropriate laboratory tests. That such a virus infection could be spread either by droplet infection or by contamination of food is not unlikely, inasmuch as it has been shown that the virus of poliomyelitis can occasionally be demonstrated in the feces of infected persons as well as in nasopharyngeal secretions. The prophylactic measures necessary in this widespread condition are, therefore, obvious. That infectious jaundice may result in serious or even fatal liver injury is fairly well recognized, but the report of Kirshbaum and Popper⁶⁵ on 15 fatal cases points to the necessity of intensive and adequate treatment of liver insufficiency in this disease. In these cases death occurred before the actual development of atrophy of the liver. Of incidental interest is the important, but not generally recognized, clinical fact pointed out by Weir,⁶⁶ who reports 10 cases of atrophy and necrosis of the liver without jaundice.

Exact information of the cause of one type of biliary tract disease, gallstones, is still lacking. There can be little doubt, however, that certain generally suspected factors play an important role in their formation. Carter and his collaborators⁶⁷⁻⁶⁸ on the basis of careful observation of clinical material point out definitely the important role of biliary stasis as a factor predisposing to the formation of gallstones. They consider that the cholesterol content of the gall bladder is not related to the cholesterol content of the blood, and that the bile salt to cholesterol ratio of the bile varies greatly in all types of pathologic change in the gall bladder. They believe that stasis is of great importance in the formation of gallstones, but point out that other unknown factors must

be operative, inasmuch as the vast majority of the noncalculous gall bladders also showed evidence of stasis. These authors also comment on the finding that in many cases gallstone formation occurred without any associated evidence of infection or inflammation of the gall bladder. Riegel, Calder and Ravdin⁶⁹ produce similar evidence that no relation can be shown between the concentration of cholesterol in the blood and the concentration of cholesterol in gall-bladder bile. That the concentration of bile acid may not be the only factor in holding cholesterol in solution in the bile, thereby preventing the formation of cholesterol calculi, is suggested by the studies of Dolkart and his associates,⁷⁰ who add further evidence to previous observations that fatty acids in the bile are probably an important factor in holding cholesterol in solution. Further evidence concerning the factor of biliary stasis, due, for example, to temporary obstruction of the common duct such as may occur from intermittent spasm of the sphincter of Oddi or from reversed peristalsis in the duodenum, is presented in experiments of Bisgard and Baker,⁷¹ who produced bile-pigment stones in goats as an indirect result of operative procedures on the common duct. A somewhat similar finding was observed by Aronson⁷² in dog experiments. The latter observer noted that such concretions obtained experimentally consisted of calcium, cholesterol, bile pigment and a large amount of unidentified black material. In an analysis of a large number of mixed human gallstones he⁷³ identified a similar dark-black residue, which contained practically no inorganic material. He believed that it probably consisted of pyrrole derivatives, degradation products of the bile pigments. Such a finding is of much interest inasmuch as material entirely similar in appearance to that described by Aronson is commonly seen in specimens of bile obtained by duodenal drainage from patients with gallstones. A rather curious and interesting finding is that of Ivy and Goldman,⁷⁴ who showed by experiments that constipation, irritation of the colon or stimulation of various divisions of the splanchnic nerves may predispose to stasis of the biliary tract by decreasing bile formation and by increasing the resistance to the flow of bile through the sphincter of Oddi into the duodenum.

It is obvious from these observations and those of Rich and Hamilton⁴² already alluded to, in which microscopic gallstones were observed in the finer biliary radicals as a result of vitamin B deficiency, that numerous factors enter into the causation of biliary calculi. To some extent, at any rate, prevention may be attempted by measures directed toward a diet adequate in all constituents, careful

bowel hygiene and the avoidance of colonic irritation by excessive catharsis or pronounced constipation, the feeding of simple fats in all meals to bring about frequent, adequate emptying of the gall-bladder contents, and the intensive and rapid treatment of any infectious or toxic process involving the biliary tract that might alter the chemical constituents of the bile because of functional hepatic disturbances.

Any adequate consideration of surgery of the gall bladder is beyond the scope of this review. Certain impressions from clinical experience and from examination of the current literature may be mentioned. The successful treatment of acute cholecystitis, a condition that is nearly always due to obstruction of the outlet of the gall bladder by calculus, still represents a controversial problem. Although some surgeons, such as Glenn,⁷⁵ consider that acute cholecystitis, like acute appendicitis, requires operation as soon as the diagnosis is made, a large number of experienced operators continue to advise a more conservative management of this condition. Graham,⁷⁶ Fallis and McClure,⁷⁷ Berk,⁷⁸ Elkin⁷⁹ and others favor a postponement of surgical measures until sufficient time has elapsed to permit a restoration of fluid balance and the institution of measures designed to protect the liver against the damage incident to anesthesia, medication and the depletion associated with this condition. It is undoubtedly true that the growing awareness of the need of such optimal preoperative preparation constitutes one of the most important contributions to modern surgery. For the most part, there is general agreement that immediate surgery is indicated only when there is evidence of a rapid spread of infection, with signs of empyema or perforation of the gall bladder. A welcome note of surgical conservatism is found in the article by O'Donnell⁸⁰ on the rationale of cholecystectomy in the noncalculous gall bladder. He reports that a careful investigation of the results in approximately 7000 patients with chronic cholecystitis who were subjected to cholecystectomy shows that over a third are complete failures. He rightly suggests that the recurrence of symptoms in cholecystectomized persons, particularly when gallstones are not present at operation, warrants the inference that an incorrect preoperative diagnosis underlies the therapeutic failure. He, like Graham and others, is skeptical of the role played by the noncalculous gall bladder in the production of symptoms, even when moderate cholecystitis can be shown to exist. There can be little doubt that gall-bladder surgery in such cases provides an example of wishful thinking and that a more adequate study will fre-

quently demonstrate that symptoms are due to simple alterations of gastrointestinal function derived from faulty bowel habits, cathartic habits, peptic ulcer, colitis, hepatitis and urinary-tract disturbances. In this respect the rather ingenious observation of Verbruyck,⁸¹ which indicates an unusual cause of right-upper quadrant distress due to disease at the hepatic flexure, is of interest. A further judicious and rather unusual surgical comment is found in the article by Warren and Balch,⁸² who discuss carcinoma of the gall bladder. There can be little doubt from the evidence provided by various articles that gallstones are present in nearly three quarters of such cases, but these authors draw what seem to be very proper conclusions; namely, that the number of patients with gallstones who develop carcinoma of the gall bladder is extremely small, and that the decision whether to operate in cases of gallstones with few or no symptoms should be governed by a consideration of the nonmalignant complications rather than by the risk of carcinoma of the gall bladder. A growing recognition of the fact that gallstones are not too infrequent in children is evidenced in the report by Seidler and Brakeley,⁸³ who report a case diagnosed by the usual methods. Their review of the literature indicates that at least 450 cases of cholelithiasis are already recorded in children under fifteen years of age.

Of importance in the diagnosis of cholelithiasis are the reports of Layne and Bergh⁶⁴ and Zollinger and Kevorkian.⁸⁵ The former have carried out a most instructive experimental study of pain in the human biliary tract induced by spasm of the sphincter of Oddi. By sudden distention of the common bile duct, pain similar to the biliary colic typical of common duct stone was produced in 29 patients. It is of interest that these subjects experienced deep epigastric or right upper-quadrant pain following such maneuvers, and in 11 cases there was an associated but delayed transmission of the pain to the right subscapular and interscapular area. In each patient, pain was associated with evidence of increased tension within the bile duct, probably secondary to the spasm of the sphincter of Oddi but not associated with any duodenal disturbance. As previously noted by Zollinger,⁸⁶ in somewhat similar experiments, nausea was occasionally observed. The clinical study by Zollinger and Kevorkian showed that in 75 cases of common duct stone slightly more than half the patients complained of right-upper quadrant pain, 40 per cent of the group localized their pain in the epigastrium, 5 per cent had left-upper-quadrant pain, and two thirds of the group also had pain in the subscapular area. Such observa-

tions are obviously important in the diagnostic interpretation of symptoms. The latter article is also of interest in that a careful comparison is made of symptoms associated with common duct stone and those in a large group of patients with carcinoma of the pancreas.

Those interested in evaluating various diagnostic tests directed toward an understanding of the degree or type of hepatic disturbance in cases of actual biliary-tract disease are referred to the appended bibliography, which includes many of the important recent articles. It is also suggested that two excellent articles by Snell⁸⁷ and Stewart⁸⁸ be consulted for additional discussion of physiologic measures designed to protect the liver from damage or to treat adequately symptoms due to existing hepatic insufficiency.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27121

PRESENTATION OF CASE

A thirty-six-year-old clerk complained of dyspnea and precordial pain.

Two years previously the patient was first troubled with palpitation and pain in the left arm. Cardiac murmurs were heard at the time, and he had been in bed almost continuously since that date. He did not improve and had dyspnea on the slightest exertion, with cough and an occasional hemoptysis. Some months before observation, he began to suffer from attacks of left precordial pain, which radiated down the left arm and through to the shoulder blades. The pain lasted for about fifteen minutes, occurred at rest, often awakened him at night, and was at first viselike, finally dwindling to a sense of oppression. Nitroglycerin gave almost immediate relief. The patient had been given aminophyllin for the last four months, which altered the pain to mere precordial oppression. Three weeks prior to observation he caught a cold, and since that time his cough and dyspnea had increased and were accompanied by a feeling of abdominal fullness and nausea with the development of ankle edema. No definite history of rheumatic fever could be elicited. One sister was known to have rheumatic heart disease.

On examination the patient was poorly developed and poorly nourished, dyspneic on the slightest exertion or talking. The neck veins were engorged. The heart was enlarged, the left border of dullness being in the fifth interspace 2 cm. beyond the mid-clavicular line. A systolic murmur could be heard in the aortic area and was transmitted to the neck; there was an associated systolic thrill. Along the left sternal border there was a loud early diastolic murmur, and at the apex a faint systolic and a very loud rumbling presystolic murmur. The pulse was 90 and irregular, the blood pressure 125 systolic, 70 diastolic. A few rales were present at the lung bases. The abdomen was distended and the liver edge palpable two fingerbreadths below the costal margin. There was no definite edema, but slight clubbing of the fingers was noted.

An electrocardiogram showed a normal rhythm at a rate of 90. There was early inversion of the T waves in Leads 1 and 2 and slight inversion of the T waves in Lead 3. There was no abnor-

mal axis deviation. The PR interval equaled 0.17 second, and the duration of the QRS complexes was 0.09 second.

The patient remained at home under the care of his physician and was given digitalis and aminophyllin, and, when necessary, nitroglycerin for pain; salyrgan on two occasions produced a good diuresis. Ten days after observation a pain of unusual severity developed in the lower back and was accompanied by marked dyspnea and cough. Morphine was ineffective, but nitroglycerin every half hour through the night gave appreciable relief. The next morning the patient ate breakfast at the table, and later his physician returned and administered salyrgan, but there was no response. Back pain and dyspnea were still present, and in the afternoon nausea developed coincident with a bowel movement; a few hours later he began to cough up blood. It was necessary for him to sit in a chair to get his breath, cough and hemoptysis persisted, and as the day wore on, the pain became so severe that he cried out in agony. It eased for a few hours, but returned in the evening, and the patient clutched his chest, obviously striving to suppress the cries that formed on his lips. Death occurred within an hour.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE: Apparently this is a case in which the patient was taken care of at home until he died, and the doctor was, I hope, puzzled about why he died, and secured an autopsy. I am equally puzzled. The patient gave no past history of rheumatic infection, heart disease or venereal disease. He had a short history of what was apparently cardiac failure, a total history of two years. He complained first of palpitation and pain of an anginal nature, dyspnea, which was severe, and hemoptysis. The pain radiated down the left arm and was relieved by nitroglycerin. It was relieved also by a drug of the xanthine series, which presumably acted as a coronary dilator.

The immediate present illness started in association with a respiratory infection, the cough and dyspnea increased, and the patient developed a little ankle edema. Examination showed an increase in venous pressure, a heart enlarged to the left, and a systolic murmur at the aortic area with a thrill, and a loud diastolic murmur along the left sternal border; it is stated that there was a very loud rumbling presystolic murmur at the apex and only a slight systolic. The rhythm of the heart, although it is described as irregular, at first appears to have been fundamentally normal from the electrocardiogram — presumably an irregularity due to premature beats. The patient had no edema at the time of this examination. He

had a slight amount of clubbing of the fingers and a blood pressure that was not very striking in view of the description of the loud early diastolic murmur along the left sternal border, that is, the diastolic pressure was not markedly decreased. Many things that would make me more comfortable in diagnosing this type of cardiac lesion are missing from this record. The patient did not have all the investigation he might have had if he had been in the hospital, so that we have to interpolate. What, for example, was the quality of the first and second heart sounds? Was there a sharp first sound with an apical diastolic murmur? Was there a diminution or absence of the aortic second sound? Was there an accentuation of the pulmonary second sound? Was there any cyanosis?

DR TRACY B. MALLORY: Dr. McGinn can answer some of these questions.

DR SYLVESTER MCGINN: The sounds themselves were not striking. The aortic second sound was almost wiped out by an early blowing diastolic murmur. At the apex, there was a faint systolic, but primarily a presystolic rumble. P_2 was greater than A_2 . The patient was not cyanotic. He had had a Hinton test in a period of hospitalization two years prior to this admission. It was negative.

DR SPRAGUE: I judge that there was a diminution of the aortic second sound, but the murmur was essentially a two-way rough murmur with a systolic thrill. There was no x-ray examination of the heart and aorta, so far as we know. The only piece of laboratory evidence in the record is the electrocardiogram. It is a popular idea that this is the only piece of information that a cardiologist must have to make a complete diagnosis of cardiac lesion, as Sherlock Holmes could tell the way a man looked by discovering the kind of cigar ashes he left around, but I assure you it is not so with the cardiologist. What do we get out of the electrocardiogram? The tracings showed that the T waves were downwardly directed in all three Leads, and the record refers to an early inversion in Leads 1 and 2. It is not possible to see these tracings. I suppose that the electrocardiogram was taken after the patient had digitalis. The T wave changes could be consistent with digitalis effect in the electrocardiogram, and the fact that it was noted as an early inversion indicates to me a sagging of the ST segment and not a late inversion of the coronary type.

DR MALLORY: Digitalis had been administered before the electrocardiogram, but the amount is not specified.

DR SPRAGUE: Concerning the absence of any abnormal electrical deviation, if we were to assume that this was an aortic lesion, and what was heard at the apex was an Austin-Flint murmur, the picture would be one of left ventricular strain, and I should expect left axis deviation. If, however, the patient had aortic and mitral lesions on a rheumatic basis, the strain on the two sides of the heart might well balance, so that there would be no disturbance in the electrical axis. The possible etiologic agents that come to mind are of course rheumatic fever and syphilis. There was no history of venereal disease, and the blood Hinton reaction was negative, there was no history of rheumatism. It does not seem as though we had to consider an arteriosclerotic, hypertensive lesion at this age, with no evidence of hypertension. I take it that no fever was connected with this episode, and it does not seem as if we have to consider bacterial endocarditis. The factors in favor of a rheumatic heart are the patient's age, and the fact that he had hemoptysis as a presenting sign. He presumably had a mitral lesion from the description of the heart murmurs. In favor of the syphilis are the fact that he came to grief quite suddenly at the age of thirty-four, with no story of previous cardiac disease, the fact that there was pain of an anginal nature as such an outstanding symptom, the obvious aortic valve disease, the description of the left ventricular enlargement without much emphasis on mitral shape to the heart, and the failure with normal cardiac rhythm. If he had only had auricular fibrillation, we could then have said right away that this was a rheumatic heart. The question of hemoptysis is perhaps an important factor here. The hemoptysis goes back two years. It is true that aneurysm of the aorta may cause hemoptysis of a small amount for weeks or even months before a final rupture, but it is much more likely that rheumatic heart disease would be the background. The last issue of the *American Heart Journal* has an analysis of fifty cases of hemoptysis in rheumatic heart disease by Wolff and Levine,* and I was interested to see in their figures that almost half of these patients (and they died within a relatively short time) had normal cardiac rhythm rather than auricular fibrillation. Wolff and Levine found that active rheumatism, pulmonary infarction and high degrees of pulmonary arteriosclerosis were the common mechanisms of hemoptysis in this rheumatic group, and pulmonary infarct was the commonest cause if congestive failure was present at the time. The average age at the onset of hemoptysis was approximately thirty-three years.

*Wolff L. and Levine H. B. Hemoptysis in rheumatic heart disease. *Am Heart J* 21: 163-171, 1941.

Then there is this terminal episode, which I may have to ask more questions about. It consists in severe pain in the lower back. Where is the lower back?

DR. MCGINN: I cannot help on that. I saw him on only one occasion. This is a history from the family.

DR. SPRAGUE: The patient had marked dyspnea and cough, which were apparently relieved by nitroglycerin. He had a condition that at least allowed him to get up and go to his breakfast the next morning. The pain and the dyspnea apparently continued, and then he started to cough up blood. The pain, I judge from the story, remained severe in his back, although we are told that he clutched his chest. Whether or not he had two pains from the same cause, I do not know. He lived for only twenty-four hours after the onset of the pain. Was this an attack of angina pectoris, or coronary occlusion, or could he have had a dissection into his aorta, or was it a good-sized pulmonary embolism, or did he have an occlusion of his aorta, or an embolic affair in some peripheral vessel, renal or mesenteric, or could he possibly have had a coronary embolism? I am going to say that he showed the rheumatic heart lesions that I have mentioned. He may have had multiple pulmonary infarcts. He may have had a complicated condition in the region of the aortic valve. Dr. Mallory has a most extraordinary collection of weird aortic lesions. It seems as if this patient had a high degree of coronary obstruction, perhaps at the coronary ostia; there might even have been some local dissection of the aorta in this region. He may have had an embolic occlusion of some branch of the aorta farther down. I always keep in the back of my mind the fact that these cases may be syphilitic because we had one man here at the age of twenty-nine on whom we made a diagnosis of rheumatic heart disease with an aortic lesion and severe angina pectoris, and a sympathectomy was done for relief. After he was operated on, the blood serologic findings came back positive, and he died suddenly thirteen days later with a very active syphilitic process in the aorta. I think all the evidence in this case, however, points in the other direction.

DR. WYMAN RICHARDSON: I want to say that the terminal events seem to me very much like a rupture of a vessel. Therefore, I should lean toward syphilis.

DR. SPRAGUE: I shall commit myself to a diagnosis of rheumatic heart disease with aortic regurgitation and stenosis and mitral stenosis. The final episode suggests a vascular occlusion or a vascular rupture. If I leaned toward syphilis, I

should say rupture, but since I have leaned toward rheumatism, I say coronary occlusion.

DR. MCGINN: The first attacks of angina pectoris apparently were associated with paroxysmal auricular tachycardia or fibrillation. Later on when I saw the patient he had an irregular pulse, apparently owing to extrasystoles, for the electrocardiogram showed no fibrillation. Aminophyllin by mouth gave very striking relief for about four months — much more than had been anticipated. When I heard of the final episode, and after having advised salyrgan, I thought it was the kidney reaction that one sees sometimes after mercurial diuretics. I telephoned the patient's house and found that the pain had preceded the injection by about eight hours, so that such a kidney reaction could not be the explanation.

CLINICAL DIAGNOSES

Rheumatic heart disease.
Congestive failure.

DR. SPRAGUE'S DIAGNOSES

Rheumatic heart disease.
Aortic regurgitation and stenosis.
Mitral stenosis and slight regurgitation.
Multiple pulmonary infarcts.
Terminal arterial occlusion, ? site.

ANATOMIC DIAGNOSES

Rheumatic heart disease, chronic, with aortic and mitral stenosis and slight tricuspid endocarditis.
Cardiac hypertrophy.
Chronic passive congestion of lungs, liver and spleen.
Hydrothorax, bilateral.
Chronic pulmonary tuberculosis, bilateral, healed apical.
Arteriosclerosis, minimal, aortic and coronary.

PATHOLOGICAL DISCUSSION

DR. MALLORY: The post-mortem examination showed rheumatic heart disease. The heart was much enlarged, weighing 640 gm. There was aortic stenosis and regurgitation and mitral stenosis, some involvement of the tricuspid valve and definite thickening without significant deformity. Both ventricles were hypertrophied, which explains the lack of axis deviation. There were no thrombi in any of the cardiac chambers and no infarction anywhere in the body. There were no pulmonary emboli. The lungs were deeply congested, with the heavy stiff texture that one sees in the most chronic type of pulmonary congestion. Very little fluid could be expressed by

pressure. There was no anatomic cause, however, for the suddenness of the terminal episode. The coronary arteries showed a few small atheromatous plaques, but nothing that caused any significant narrowing. On the posterior surfaces of the aortic cusps there were large calcareous masses projecting into the sinuses of Valsalva. The question has often been raised in such cases whether these masses ever impinge on the coronary ostia. Since the blood flow in the coronaries occurs in diastole, one would expect the aortic ring to be stretched to its limits at this time, which seems a little unlikely.

DR. SPRAGUE: I wonder how nitroglycerin could relieve a person with angina pectoris based on obstruction in the sinuses of Valsalva. Could it, by peripheral vascular relaxation, open up the sinuses?

DR. MALLORY: I do not know. It should lower the blood pressure and collapse the aorta rather than dilate it further. Certainly I think one can say that there was no good anatomic evidence of any coronary narrowing, despite the long history of angina.

CASE 27122

PRESENTATION OF CASE

A fourteen-year-old-boy entered the hospital complaining of pain in the right knee.

The patient felt well until six weeks before admission, when he became tired, easily fatigued and complained of general malaise. A week later and coincident with a chill he noticed pain in his right knee while walking; it increased in severity over the next few days to a point where it was present at rest. At this time he developed a cold; weakness, general malaise and pain increased, so that he went to bed of his own volition and remained there until the time of admission. During the weeks before entry, he suffered from several chills, night sweats and anorexia. The pain in the knee was aggravated by motion and varied in severity, so that sometimes even the weight of the bedclothes hurt. "The pain went off and on like a light flashing." For two or three days two weeks before admission fleeting pains developed in the right hip and ankle and in the muscles of the leg, lasting for perhaps four or five minutes and then fading. At this juncture the patient also noticed that he was unable to extend his knee fully. No history of trauma could be elicited. The patient stated that he had been subject to furuncles and boils for some time. There had been a weight loss of 15 pounds since the beginning of the illness.

One sister was being treated for rheumatic fe-

ver. A year previously the patient had been examined in another hospital, but apparently no abnormalities were found.

On physical examination the patient was rather poorly developed and poorly nourished, and he looked tired and ill. Two small furuncles were present on the upper lip, and one on the lower. The heart, lungs and abdomen were normal; the blood pressure was 125 systolic, 68 diastolic. There was a 4.4-cm. atrophy of the right thigh, but no wasting of the calf. The right knee was held in 20° flexion, but could be corrected passively. Free motion was present between 20° and 75° flexion without discomfort, but beyond these points pain was felt. At the medial aspect of the lower end of the right femur immediately proximal to the femoral condyle, there was a firm, slightly tender fullness. There was no redness or obvious increase in skin temperature over this fullness; the knee joint did not appear to be involved in the process, and there was no increase in fluid or thickening of the synovia.

The temperature was 101.5°F., the pulse 120, and the respirations 24.

The urine was normal. Examination of the blood showed a red-cell count of 4,700,000 with a hemoglobin of 75 per cent, and a white-cell count of 14,000 with 87 per cent polymorphonuclears. The sedimentation rate was 42 mm. in one hour. The serum protein was 7.3 gm., the calcium 9.9 mg. and the phosphorus 4.8 mg. per 100 cc., and the phosphatase was 6.3 Bodansky units. A blood Hinton test was negative, the tuberculin test was negative in dilutions of 1:10,000, 1:1,000 and 1:100.

An x-ray film of the knee showed an area of destruction in the distal medial end of the right femur close to the epiphyseal line, but not crossing it. The cortex showed destruction in parts, and there was periosteal new-bone formation along the extent of the lesion, with some amorphous areas of calcification in the soft tissues outside the stratified new-bone formation. Some soft-tissue swelling was present, but a definite soft-tissue mass was not outlined.

For the next few weeks the temperature ran between 99 and 101°F., and the white-cell count averaged 12,000. Three weeks after admission an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. THOMAS J. ANGLEMI: May we see the x-rays?

DR. GEORGE W. HOLMES: I am familiar with the case, and I cannot improve very much on the description in the text. I might point out one

or two things. First, the lesion does not cross the epiphyseal line, and we stressed that fact in our report. It is true that tumors are less likely than infections to cross an epiphyseal line, but infections do not always cross the line. I think that sign has been overevaluated. The process in the bone is largely destructive. There is rather more destruction than new-bone formation. The primary process is a destructive one, with reaction in the periosteal tissue around it, which is a little in favor of infection. I think the benign tumors are out; we do not need to discuss them to any extent. To my mind the problem is between an infection and a malignant tumor. I should also call attention to the character of this proliferation. That is typical spicule formation such as one sees in malignant tumor. It can occur in infections, but it is not typical.

DR. GRANTLEY W. TAYLOR: Do you want to comment on the presence or absence of the soft-part tumor in association with this, or the presence of edema in the subcutaneous tissue?

DR. HOLMES: Soft-tissue tumor is much more likely to be present in a malignant tumor than it is in an infection. It is a localized, sharply defined tumor, whereas in infection there is diffuse swelling and edema over the whole area; however, edema may occur in malignant tumors, and it may sometimes be absent in infection. It is only a matter of probability. Of course, the amount of swelling in this case is not what one would expect to see in a large malignant tumor. We thought that there was some edema. There is no well-defined soft-tissue tumor.

DR. ANGLEM: This record at first reading left me with a very strong impression that we were dealing with an acute hematogenous osteomyelitis that had passed over into a subacute or semi-chronic phase. We have a boy of fourteen, an age when this disease is common. He complained of fatigue and malaise, following which he had the sudden appearance of pain in the right knee, which was ushered in with a chill. The pain increased in severity in succeeding weeks. Then he had additional chills, night sweats and anorexia, and shortly before admission he was unable to extend his knee. On admission his temperature was 101.5°F., the white-cell count 14,000 with 87 per cent polymorphonuclears, and there was a mild anemia. On examination of the knee, we found that on palpation a firm, slightly tender fullness was observed, without redness of the skin over the area and with no evidence of joint involvement, no evidence of reactive synovitis or of fluid in the joint.

There are certain inconsistencies, however, that

raise some doubt of the correctness of this diagnosis. For example, this boy is said to have had pain that increased over the first few days after the onset, and at the end of a few days was present at rest. In other words, we must conclude that then he was up and about, which we should hardly expect him to be if he had come down with osteomyelitis from an organism of sufficient virulence to cause chills. He apparently did not take to bed until several days after the onset, when malaise and weakness finally made their appearance. In other words, the toxemia that we associate with acute hematogenous osteomyelitis must have been absent or very slight. We might explain that by assuming that the organism was of low virulence. If that were true, we should hardly expect the sudden onset with chill; we should like to know more about the chills. Were they genuine rigor or merely chilly sensations that might be associated with any fever? We should also like to know if a blood culture was taken, and if so, what the report was.

DR. TRACY B. MALLORY: There were no blood cultures. Here is the preoperative chart. The highest recorded rectal temperature is 101°F., and the highest by mouth is 100.

DR. ANGLEM: What other possibilities are there? I still reserve judgment, but I think that at least there is some doubt as to the presence of a pyogenic infection here. The negative blood Hinton test and a negative tuberculin in a dilution of 1:100 make it unnecessary to regard seriously either syphilis or tuberculosis. The clinical course is not typical of either. Syphilis of bone would be extraordinarily rare at this age, and the location of the lesion in the metaphysis rather than the epiphysis is against the diagnosis of tuberculosis. The malignant tumor that is most likely to simulate osteomyelitis and to be confused with it is Ewing's sarcoma. It is very frequently characterized by fever, leukocytosis and pain such as is present in this case; but the mode of onset in most cases is quite different from what we have observed here. The characteristic syndrome is one of rather mild pain coming on intermittently at intervals over a long period of time—several months, even as long as a year. The intervals of pain may or may not be associated with fever and leukocytosis, but in most cases there is a rather long duration of the illness before the patient is finally obliged to take to bed, in contrast to a few days in this case. Moreover, Ewing's tumor in the vast majority of cases, although we have just seen an exception, is situated in the shaft of the bone, and this lesion does not seem to me particularly to suggest Ewing's sarcoma by x-ray, al-

though I do not believe it can be ruled out entirely. This disease does occur in this area in rare cases and can present itself in atypical forms that are difficult to diagnose. I neglected to mention, and it may be of some importance later in the discussion, that the patient described the pain as "coming on and off like a light flashing"; we are more accustomed to see that type of pain associated with tumor than with osteomyelitis. To go back to Ewing's tumor again, it is most often confused with the subacute or chronic type of osteomyelitis, which we might well have here.

In contrast, osteogenic sarcoma in certain forms is likely to simulate an acute osteomyelitis in onset. Unlike Ewing's tumor, the pain, once it starts, is persistent with no letup for any appreciable length of time. Certain forms of osteogenic sarcoma are associated with fever and leukocytosis and pain, particularly the osteolytic type, which occurs in young people frequently in and around this age—fourteen to twenty. We have to consider it seriously here, and in support of this diagnosis and against the diagnosis of osteomyelitis I think we might point out that nowhere in the history is there any indication of appreciable swelling, redness or marked tenderness in association with this lesion, which at the time of examination was described as a slightly tender fullness with no real appreciable swelling. So far as we know the skin was not red, and there was no inflammatory reaction in the adjacent joint. All these factors, I believe, are in accord with the diagnosis of tumor rather than osteomyelitis. The x-ray picture can fit either diagnosis.

I think that the diagnosis in this case hinges on interpretation of the story, particularly the story of chills. If we knew definitely that these were real shaking chills, I should favor strongly the diagnosis of osteomyelitis that has gone over into a subacute phase, but I am inclined to dis-

count the story of chills and furuncles because of the peculiar way in which the point is interjected into the story. It is said that at some time in the past the patient had furuncles, but there is no definite indication that he had furuncles immediately preceding these symptoms. I hesitate to discount the story of chills, but considering the whole picture I should favor a diagnosis of osteolytic osteogenic sarcoma.

CLINICAL DIAGNOSIS

Bone tumor?

DR. ANGLE'S DIAGNOSIS

Osteogenic sarcoma, osteolytic type.

ANATOMICAL DIAGNOSIS

Subacute osteomyelitis of the femur.

PATHOLOGICAL DISCUSSION

DR. MALLORY: The preoperative consensus was that this was a malignant tumor, but a good deal of difference of opinion was expressed. Have you any comment, Dr. Taylor?

DR. TAYLOR: No, I think Dr. Anglem discussed all the points and more than the ones we took into consideration.

DR. HOLMES: May I ask whether he had any chemotherapy?

DR. MALLORY: I think not. I can see no report of it.

It was decided to biopsy this lesion with a pathologist on hand for a frozen section, and to be prepared for amputation, if it should be necessary. At the biopsy, frank pus was found, and cultures showed *Staphylococcus aureus*. The material curetted from the margins of the cavity showed acute and chronic inflammation, so that I think tumor is certainly ruled out.

MEDICAL ADVISER TO THE MASSACHUSETTS DEPARTMENT OF PUBLIC WELFARE

THE appointment of a medical adviser to the Massachusetts Department of Public Welfare, as noted elsewhere in this issue of the *Journal*, is an important step forward, with many implications as to future developments. The well-known relation between poverty and disease, with a consequent overlapping, makes this position a crucial one. It has been assumed that there is a causal link between poverty and disease, some emphasizing poverty as a cause of disease, and others, disease as a cause of poverty. Although both these points of view are undoubtedly to some extent justified, it is perhaps also true that they are but twin

sisters of those great parents of all misery—ignorance and vice.

The profession awaits with interest the developments that will come from this appointment.

ROBERT FORTESCUE FOX

IN the death of Dr. Robert Fortescue Fox, of London, England, on June 15, 1940, in his eighty-second year, there passed one of the most significant influences operative in the world toward bringing about that acceptance of the importance of the rheumatic diseases which exists today and is everywhere on the increase. Dr. Fox came of a medical family and was a member of the Society of Friends. His personality and work were characterized by those qualities of kindness, consideration and purpose which the world has learned to associate with that sect, and he was buried very near the grave of one of the greatest apostles of the order, William Penn.

Perhaps partly as a result of his own early struggle with tuberculosis, he was something of a medical fundamentalist and entertained a profound belief in the efficacy of natural defenses and agents, when properly co-ordinated, in the treatment of disease. Using physical agents, first empirically and later on the basis of controlled observations, he became an authority in the field of physical therapy and spa treatment. Of him Sir Humphry Rolleston writes, "He was a gentle though persistent pioneer of physiotherapy and spa treatment, persuasive by his convictions rather than dictatorial."

In addition to numerous contributions to medical literature, Dr. Fox was the founder and editor of the *Archives of the International Society of Medical Hydrology*. He was a leading spirit in starting in London the Red Cross center for the treatment of rheumatic diseases and was active in the development and provision of adequate facilities for the care of ex-service men.

Active to the last, he recently advocated a program for a Committee for Research on Delicate Children, and on the day of his death a letter appeared from him in the London *Times* on the need

for a properly organized system of physical treatment for the troops.

Dr Fox's greatest contribution was probably in connection with his untiring and persistent efforts in founding, with Dr J van Breemen, of Amsterdam, Holland, prior to 1926, the Ligue Internationale contre le Rhumatisme, of which he served as president for many years, retiring after the brilliant sixth congress of the Ligue held in London, Oxford and Bath in March and April, 1938

As a practical idealist he encountered much resistance but lived to see his labors bear wide fruition. It can fairly be said that the pivotal role played by Dr Fox as a pioneer in the field of rheumatic diseases will gather rather than lose significance when the history of the movement to control these disorders is written

MEDICAL EPONYM

GULL'S DISEASE

The article, "On a Cretinoid State Supervening in Adult Life in Women," which has bound the name of Sir William W Gull (1816-1890) to this condition, was read before the Clinical Society of London on October 24, 1873, and appears in the *Transactions* of that society (7: 180-185, 1874)

The remarks I have to make upon the above morbid state are drawn from the observation of five cases. Of two of these I am able to give many details, but the three others were only seen by me on one or two occasions

CASE I

Miss B after the cessation of the catamenial period, became insensibly more and more languid, with general increase of bulk. This change went on from year to year, her face altering from oval to round, much like the full moon at rising. With a complexion soft and fair, the skin presenting a peculiarly smooth and fine texture was almost porcelainous in aspect, the cheeks tinted of a delicate rose purple, the cellular tissue under the eyes being loose and folded, and that under the jaws and in the neck becoming heavy, thickened and folded. The lips large and of a rose purple, alae nasi thick, cornea and pupil of the eye normal, but the distance between the eyes appearing disproportionately wide, and the rest of the nose depressed, giving the whole face a flattened broad character. The hair flaxen and soft the whole expression of the face remarkably placid. The tongue broad and thick, voice guttural, and the pronunciation as if the tongue were too large for the mouth (cretinoid). The hands peculiarly broad and thick spade-like, as if the whole textures were infiltrated. The integuments of the chest and abdomen loaded with

subcutaneous fat. The upper and lower extremities also large and fat, with slight traces of oedema over the tibiae, but this not distinct, and pitting doubtfully on pressure. Urine normal. Heart's action and sounds normal. Pulse, 72, breathing, 18

Such is a general outline of the state to which I wish to call attention

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

MATERNAL MORTALITY IN MASSACHUSETTS

The cases that have been appearing in the *Journal* on obstetrics and its complications have come in most part from the files of private cases in the practice of members of the Committee At Large of the Section of Obstetrics and Gynecology. They have been grouped to illustrate specific conditions. Beginning with this issue and continuing for an indefinite time, cases will be reported from the Maternal Mortality Study in Massachusetts during the last four years. In general, the form of the cases already reported will be followed, of necessity some details may be absent. No attempt will be made to group cases according to specific complications. All these cases, of course, were fatalities

A twenty eight year-old primipara was said to have been seen when about three months pregnant. The physical examination at that time was essentially negative. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The pelvic measurements were normal. The blood pressure was said to be normal. The uterus was enlarged to a size consistent with the period of amenorrhea.

The patient was seen in the fifth and seventh months but not again until labor started at term by the rupture of the membranes. After a labor, which was said to have been only four hours in duration, an attempt at forceps delivery was made. When this procedure was unsuccessful, a version was attempted. It was reported that a contraction ring was present and that the patient bled very freely. A consultation was held, but the patient died undelivered.

Comment This case represents obstetrics at its worst. The prenatal care was absolutely inadequate.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

quate. The patient was seen but three times during her pregnancy, and an interval of at least six weeks occurred between the last visit and the onset of labor. The consultant believed that the pelvis was adequate, so that the need of an elective cesarean section because of definite disproportion did not exist. It is conceivable that a primipara after four hours of labor might attain full dilatation. The history of this case suggests that this was not so. Had complete dilatation been present with a head well engaged, it is impossible to believe that forceps delivery would have failed. That it did fail leads one to the probable inference that complete dilatation was not present, and that in an attempt to dilate the cervix manually so that forceps could be applied the head was disengaged and made the operation difficult even in the hands of the best-trained men. When in the hands of the operator forceps were found inefficient and version was attempted, it is most likely that the uterus was ruptured, causing excessive external and concealed hemorrhage. Such results can in no way be justified, and so long as hospitals in Massachusetts allow such procedures and do not regulate all obstetric operating, these results will be repeated.

COMMITTEE ON STATE AND NATIONAL LEGISLATION

At its meeting on February 5, the Council voted to oppose the following bills, which have been reported favorably by the Committee on Public Health:

H. 114. Bill (accompanying House No. 113, recommendations of the Board of Registration in Medicine) relative to providing for the annual registration of physicians and the biennial publication of the list of physicians duly registered.

H. 115. Bill (accompanying House No. 113, recommendations of the Board of Registration in Medicine) relative to the recording of the certificate of registration of a qualified physician by the town clerk.

H. 116. Bill (accompanying House No. 113, recommendations of the Board of Registration in Medicine) relative to establishing a special commission to investigate and study the advisability and practicability of requiring special qualifications of all physicians who engage in the practice of surgery.

H. 114 and H. 115 have been referred to the Committee on Ways and Means, whose members are as follows:

Committee on Ways and Means: Senators Arthur W. Hollis, 90 Washington Street, Newton, Senate Chairman; Harris S. Richardson, 15 Mt. Pleasant Street, Winchester; Cornelius F. Haley, Main Street, Rowley; Laurence Curtis, 15 River Street, Boston; Joseph L. Murphy, 57 Samoset Street, Boston.

Representatives Albert F. Bigelow, 246 Dudley Street, Brookline, House Chairman; Walter R. Baylies, 48 William Street, Taunton; James A. Peckham, 2 Upland Road, Wellesley; Paul W. Foster, North Plain Road, Great Barrington; Douglass B. Francis, 35 Meadowbrook Road, Newton; Albert Bergeron, 35 Mt. Vernon Street, Lowell; Charles H. Roberts, Jr., Salem End Road, Framing-

ham; Robert S. Backus, Nantucket; Nathaniel Tilden, 37 Elm Street, Scituate; Richard J. White, Jr., 8 Upham Road, Lynn; Anthony R. Doyle, 150 Beacon Street, Worcester; James F. Tobin, 117 Mason Street, Salem; Patrick G. Sullivan, 92 Codman Hill Avenue, Dorchester; Joseph H. Downey, 254 Main Street, Brockton; Jeremiah D. W. Crowley, 462 Washington Street, Brighton.

H. 116 has been referred to Committee on Rules, the members of which are the following:

Committee on Rules: Senators Angier L. Goodwin, 33 Reading Hill Avenue, Melrose, Senate Chairman; Jarvis Hunt, 51 High Street, North Attleboro; Newland H. Holmes, 83 Webb Street, Weymouth; Donald W. Nicholson, Highland Road, Wareham; Mason Sears, West Street, Dedham; David M. Brackman, 52 Brookledge Street, Dorchester; Chester A. Dolan, Jr., 987 Parker Street, Jamaica Plain.

Representatives Christian A. Herter, 61 Beacon Street, Boston, House Chairman; William A. Jones, Main Street, Barnstable; Rudolph F. King, 163 Exchange Street, Millis; Alfred M. Bessette, 171 Query Street, New Bedford; William R. Gilman, 83 Fellsmere Road, Malden; William A. Akeroyd, Prospect Street, Lanesborough; Fred A. Hutchinson, 36 Savory Street, Lynn; Hiram N. Dearborn, 86 Electric Avenue, Somerville; Nelson B. Crosby, 10 Davis Avenue, Arlington; Fred B. Dole, Shelburne; John E. Troy, Jr., 54 Pleasant Hill Avenue, Dorchester; Joseph N. Roach, 561 Main Street, North Adams; Andrew J. Coakley, 19 Bell Street, Chicopee.

If the members of either of these committees come from your district, be sure to write to them, asking them to defeat the bills in their committee, and in any event, write to your representative and ask him to vote against the bills when they reach the floor of the House of Representatives.

The following bill is scheduled for hearing at the State House during the week of March 24:

March 27

H. 870 (Public Health). Petition of the Massachusetts Mothers' Health Council for legislation to protect working women before and after childbirth. The aims and purposes of this bill are endorsed. *Favored.*

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 23:

BERKSHIRE

Thursday, March 27, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. Chemotherapy in the Treatment of Gonococcal Infection. Instructor: Weston T. Buddington. Harry G. Mellen, Chairman.

BRISTOL SOUTH (Fall River Section)

Tuesday, March 25, at 4:30 p.m., at the Union Hospital, Fall River. Obstetric Complications, with Case Histories and Clinical Problems. Instruc-

tor James C Janney Howard P Sawyer,
Chairman

ELLEN

Thursday, March 27, at 8 00 p.m., in the Library of the Franklin County Public Hospital, Greenfield Management of Abdominal Distention In-
structor Hollis L. Albright Halbert G Stetson,
Chairman

PDEN

Wednesday, March 26, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p.m., in the Out patient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Diagnosis and Treatment of Minor Lesions in Rectum and Anus
Instructor E. Parker Hayden Alfonso A Palermo, *Chairman*

PSHIRE

Thursday, March 27, at 4 15 p.m., in the Nurses Home of the Cooley Dickinson Hospital, Northampton Infections of the Hands and Feet.
Instructor William E Browne Robert C Byrne,
Chairman

CESTER

Tuesday, March 25, at 8 30 p.m., in the Nurses Home of the Milford Hospital, Milford Pediatric Case Discussions Instructor Warren R Sis-
son Joseph Ashkins, *Chairman*

CESTER NORTH

Friday, March 28, at 4 30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg Technique and Treatment of Primary, Secondary and Tertiary Syphilis Instructor Rudolph Jacoby
George P Keaveny, *Chairman*

ATHS

CLEAVES—EDWIN N CLEAVES, M.D., of Boston, died January 24. He was in his fifty-second year. Dr Cleaves received his degree from Harvard Medical School in 1915. He was a member of the Massachusetts Medical Society, the American Medical Association, the American Roentgen Ray Society, the New England Roentgen Ray Society and the American College of Radiology.

SHEA—PETER O SHEA, M.D., of Worcester, died March 9. He was in his seventy-second year. Born in Worcester, he graduated from Holy Cross College and received his degree from Columbia University College of Physicians and Surgeons in New York City in 1895. He received an M.A. degree from Holy Cross College in 1896.

Dr Shea was a former trustee of the Grafton State Hospital having served for six years in that capacity. He was Director of the Board of Health at Worcester at the time of his death and had been a member of the Board since 1925. He was a fellow of the Massachusetts Medical Society and of the American Medical Association. His daughter, a sister and a brother survive him.

SIMMONS—LT COL. RALPH H SIMMONS, M.D., of Fort Adams Rhode Island, died March 13 at the Walter Reed Hospital Washington, D.C. He was in his fifty-third year.

Born in Brockton, he attended the local schools there and received his degree from Tufts College Medical School in 1913. For the next three years he was resident physician at the Union Hospital, Fall River. He had served overseas during World War I and at the time of his death was post surgeon at Fort Adams, Rhode Island.

He was a fellow of the Massachusetts Medical Society and the American Medical Association, and held memberships in the American Academy of Ophthalmology and Oto-Laryngology and the American College of Surgeons.

His widow, a son and two sisters survive him.

WORTHING—FRANK B WORTHING, M.D., of Chatham died March 13. He was in his seventy-second year.

Born in Hallowell, Maine he received his degree from the Bowdoin Medical School in 1896. He was a member of the Massachusetts Medical Society, the American Medical Association and the Cape Cod Medical Association.

His widow, a daughter and a son survive him.

MISCELLANY

MEDICAL ADVISER TO THE MASSACHUSETTS DEPARTMENT OF PUBLIC WELFARE

Dr B W Mandelstam was recently appointed medical adviser to the Massachusetts Department of Public Welfare. Born in Boston, he graduated from Tufts College Medical School in 1932 and later served an internship at the Lynn Hospital. Then followed seven years of active general practice in Bridgewater, where he had an opportunity for close contact with the medical problems of welfare recipients and welfare boards, as well as insight into the physician's attitude toward these problems. He will act as an adviser to the department in all matters relating to medical care. It is hoped that this appointment will be an aid to the medical profession in the recognition that welfare activity is both a professional and civic duty. It is also hoped that the profession will co-operate with him and the department in keeping such care on a high professional plane, at the lowest possible cost, as a means of continuing our present system of free choice of physician.

Plans have been made for the appointment of an advisory committee to be composed of persons representing the various professions concerned with the medical care of the needy, as an aid to working out a satisfactory program.

IMPORTANCE OF THE TUBERCULIN TEST

Methods for finding cases of tuberculosis have not yet been reduced to a standardized pattern. Experience has prompted certain changes, and practical considerations make it necessary to eliminate wasteful methods. Pressed by the need for economy some workers now place almost sole reliance on the x-ray and seem ready to discard the tuberculin test as a selective screen. Among those who believe that the tuberculin test is still of great importance is Myers. In a recent paper (Tuberculosis in students, *Am Rev Tuberc* 43 235 244, 1941) he delineates his conception of tuberculosis, which some may not accept in practice but which furnishes food for thought. An abstract of the discussion follows.

Ten years ago to say that a student had tuberculosis really meant that he had consumption. It was the tuberculosis diagnosed by the ancient Chinese, Babylonians

Greeks and all since their time. A more recent and more logical conception of tuberculosis is that it begins when the first neutrophil phagocytizes a tubercle bacillus, and that the outcome depends on subsequent physiologic events. From three to seven weeks after tubercle formation begins, the tissues are sensitized to the protein fraction of the tubercle bacillus, and apparently remain sensitized so long as tubercle bacilli are alive in the body. This sensitivity is determined by the tuberculin test. The tubercles may be microscopic in size, and there is no way of determining in a given person whether clinical tuberculosis will ever make its appearance. Since the body is seeded with tubercle bacilli, clinical lesions may appear at any time and in almost any place. Therefore, all who react to tuberculin have tuberculosis.

The acceptance of this idea is imperative, says the author, because it is the only conception that will lead us to the control of the disease. Normal appearance and normal x-ray shadows in a positive reactor do not justify looking lightly on the condition. Inspection of the chest does not include the entire lung, and some lesions may be too small to cast shadows. Moreover, clinical tuberculous lesions may develop in many parts of the body other than the lung.

Even if we could be certain that in the tuberculin reactors there are at the moment no lesions except those of the primary complexes, we have no way of determining what minute acute or chronic clinical lesions will develop or where they will be located. The reactor whose complete examination is negative today may have tuberculous meningitis, miliary disease, tuberculous pneumonia, peritonitis, pleurisy with effusion or synovitis, tomorrow.

Chronic clinical tuberculosis is essentially a disease of adults—it begins to get into its stride only in the college and university age period. Therefore, one finds only a small percentage of positive tuberculin reactors with chronic, clinical tuberculous lesions during their few student years, yet it is of great importance that their disease be detected before it becomes contagious.

Occasionally one asks why it would not be better to omit the tuberculin test and proceed directly to the x-ray film inspection of the chest, since the occasional person has spoken of this inspection as the best case-finding method. No student of tuberculosis could be satisfied with such a procedure because the x-ray film examination is totally inadequate in determining the true tuberculosis situation in any student body. Such examination is limited to a small part of the body; indeed, it does not include more than 75 per cent of the lungs themselves. Moreover, it reveals evidence only of gross lesions and does not differentiate these with reference to etiology, tuberculous or nontuberculous. We divide pathology into gross and microscopical for teaching and practical purposes. The x-ray reveals only the gross. For example, among those who have primary tuberculosis complexes in the body, the x-ray film of the chest reveals evidence of their presence in only approximately 10 to 15 per cent. The student of tuberculosis demands something far more delicate than the x-ray film and he finds it in the tuberculin test.

It would be as futile to try to control tuberculosis without the tuberculin test as to try to control syphilis without the Wassermann or an equally good test. At the University of Minnesota we have in the neighborhood of 4500 entering students each year and the tuberculin test indicates that approximately 1000 of them have the first-infection type of tuberculosis somewhere in their bodies; that is, primary tuberculosis complexes have been established, and to us the tuberculin reac-

tion means that living tubercle bacilli are present. Among our reactors, only 100 to 150 present any evidence that might be interpreted as representing the primary tuberculosis complex on the x-ray film of the chest. Of the entire 1000, rarely more than 10 to 15 have, at the moment, lesions in the lungs which cast shadows that might be due to the clinical form of pulmonary tuberculosis. Thus, if we depended entirely on the x-ray film examination, we would overlook 85 per cent or more of the students who actually have tuberculous lesions in their bodies. Each of the 1000 students who reacts to the tuberculin test is a potential clinical case of tuberculosis some time in life and in the occasional one this form of the disease will actually occur while in school. Therefore, we feel that this group of 1000 students should be listed and observed from year to year for clinical tuberculosis, just as one lists those who have not been immunized against smallpox or diphtheria as the susceptibles in case of an outbreak of one of these diseases on the campus.

Experience in eradicating tuberculosis in cattle justifies our faith in the tuberculin test.

The veterinarians of this country have made more than 217,000,000 tuberculin tests on cattle between 1917 and 1939. The carcasses of more than 3,700,000 reactors were examined postmortem, and the accuracy with which the test selected those with tuberculous lesions was little short of miraculous. Indeed, it was only through the tuberculin test as the detective that tuberculosis has been almost eradicated from the cattle herds of this nation.

Of course no tuberculosis program is complete that stops with the tuberculin test. Reactors should have a chest x-ray examination, preferably by film inspection, although the fluoroscope in the hands of an expert may equal the film inspection. Those students with shadows of lesions must be examined in considerable detail, and in those with shadows that persist, laboratory examinations, including the search for tubercle bacilli in the gastric contents, must be made.

The author gives the following answer to the question, Must students contract tuberculosis while in college?

No, because we have at our command accurate methods of screening our contagious cases of tuberculosis in any group. Therefore, if we keep students under sufficiently close observation, it is with great rarity that one will enter with contagious disease or will develop it on the campus so as to disseminate it to other students. Thus, the students may be prevented from contracting tuberculosis from one another. . . . It is true that the occasional student will become infected through contact with a contagious case entirely apart from the campus. However, in most parts of this country such infections have been reduced to one per cent or less per year. Therefore, few students become infected even in this manner while they are in college.—Reprinted from *Tuberculosis Abstracts*, March, 1941.

NOTICES

HARVARD SCHOOL OF DENTAL MEDICINE

Harvard University announced recently the opening of a five-year course combining medical and dental training. The new school of dental medicine was established for the purpose of training new types of scientific workers, combining the skills of both medicine and dentistry. Next fall, with the opening of the new school, dental students will register in both the School of Dental Medi-

and in the Harvard Medical School for a five year course, taking approximately three and a half years of same medical courses as other students in the medical school, and, in addition, an amount of specific dental training sufficient to qualify them for dental practice graduates will receive both the MD and the DMD degrees

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway, Boston, Monday, March 24, at 8 15 p m Professor J Walter Wilson, of the Department of Biology, Brown University, will speak on "The Role of Art in the Development of the Natural Sciences in the Renaissance" All interested persons are cordially invited to attend the meeting

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, March 25, at 5 00 p m

PROGRAM

- Decrease in Cardiac Efficiency Due to Varicose Veins Dr E M Chapman
- The Effect of Evipal upon Two Major Respiratory Drive Mechanisms Drs C A Moyer and H K Beecher
- Mechanisms of Respiratory Failure under Barbiturate Anesthesia (Evipal, Pentothal) Drs H K Beecher and C A Moyer.

TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

Professor W Barton Leach, of the Harvard Law School will be the guest speaker at the annual Tufts College Medical Alumni Dinner, at 7 p m, on Wednesday evening, March 26, at the Hotel Somerset. He will discuss "The International Position of the United States and What Do About It." Dr James W Manary, superintendent of medical director of the Boston City Hospital, will preside

Other speakers on the program are Dr Leonard Carichael, president of Tufts College, who will report on the developments to date of the fund raising campaign, Dr Frank R. Ober, who will tell of the Medical Alumni Council's reorganization, and His Honor, Mayor Maurice Tobin, who will bring the greetings of the city of Boston

The dinner will also serve as a special reunion for members of the 1916 class, celebrating their silver anniversary. Simultaneously, the Rhode Island Tufts Medical Club will combine the activities of its annual meeting with the dinner. Dr Harmon P B Jordan, superintendent of the Providence Lying In Hospital, and Dr Charles Gormly, physician-in-chief of the Rhode Island Hospital, Providence, head the Rhode Island delegation

ROBERT DAWSON EVANS MEMORIAL LECTURE

Dr Allen O Whipple, professor of surgery at Columbia University College of Physicians and Surgeons, will give the third in a series of four Robert Dawson Evans Memorial lectures on Friday, March 28, at 8 15 p m, in the Evans Auditorium, 78 East Concord Street, Boston. His subject will be "A Discussion of Certain Splenopathies in Relation to the Vascular Bed of the Spleen" Physicians and medical students are cordially invited to attend

MASSACHUSETTS PSYCHIATRIC SOCIETY

The next meeting of the Massachusetts Psychiatric Society will be held at the Massachusetts General Hospital on Friday, March 28, at 8 p m

PROGRAM

- The Anticonvulsive Action of Neoprontosil Drs Stanley Cobb and Mandel E Cohen
- The Conditional Salivary Reflex in Psychoneurotic Patients Drs Jacob E Finesinger and George F Sutherland
- The Evaluation of Changes in Mental Status Produced under Laboratory Condition Dr Erich Linde mann
- Studies in Muscular Tension in the Neuroses Dr Jurgen Ruesch

NEW ENGLAND SOCIETY OF PSYCHIATRY

The annual meeting of the New England Society of Psychiatry will be held at the Fairfield State Hospital, Newtown, Connecticut, on Thursday, April 10. Dr Arthur H Ruggles, superintendent of the Butler Hospital, Providence, Rhode Island, will speak on the subject "Work Therapy Its importance to the patient and to the hospital"

HERMANN M BIGGS MEMORIAL LECTURE

The Hermann M Biggs Memorial Lecture, given under the auspices of the Committee on Public Health Relations of the New York Academy of Medicine, will be delivered by Dr C A Mills, professor of experimental medicine, University of Cincinnati, at the New York Academy of Medicine, on Thursday, April 3, at 8 30 p m. Dr Mills will speak on "The Relation of Climate and Geography to Health"

The medical profession and the public are cordially invited to attend

NEW ENGLAND HEALTH INSTITUTE

The New England Health Institute will be held in Boston on Wednesday, Thursday and Friday, April 2-4. All lectures will be at the Hotel Statler. The Wednesday evening session will be devoted to talks on public health in its relation to national defense measures. Dr Paul J Jakmauh, Commissioner of Public Health in Massachusetts, will preside at this meeting, at which Dr Thomas Parran, Surgeon General, U S Public Health Service, and Miss Katherine Lenroot, Chief, Children's Bureau, U S Department of Labor, will be the speakers. On Thursday evening a dinner and dance will be held at the Hotel Statler. Brigadier General Frederick F Russell, of the

U. S. Army Medical Reserve Corps, will be the speaker at the dinner.

The three-day institute is divided into sixteen sections, covering every field of health work. Four sessions will run concurrently every hour from 9:30 a.m. to 12:30 p.m., and from 2:00 p.m. to 5:00 p.m. The various sections and chairmen are as follows:

SECTIONS	CHAIRMEN
Public-Health Administration	Travis P. Burroughs, M.D., Stanley H. Osborn, M.D.
Cancer and Chronic Diseases	Ludvig Hektoen, M.D., Sc.D.
Communicable Diseases	Roscoe L. Mitchell, M.D., Charles F. Dalton, M.D., Lester A. Round, Ph.D.
Crippled Children	Robert C. Hood, M.D.
Environmental Sanitation	Arthur D. Weston, C.E.
Food and Drugs	Harry E. Barnard, Ph.D.
Genitoinfectious Diseases	Raymond A. Vonderlehr, M.D.
Health Education	Ira V. Hiscock, Sc.D.
Laboratory	Friend Lee Mickle, Sc.D.
Maternal and Child Hygiene	Martha M. Eliot, M.D., Francis V. Corrigan, M.D.
Nutrition	Helen Hinman, S.B.
Occupational Hygiene	Philip Drinker, S.B., Ch.E.
Public-Health Nursing	Pearl McIver, R.N. Hazel V. Dudley, R.N.
School Health	Walter F. Downey, M.Ed.
Tuberculosis	Henry D. Chadwick, M.D.
Vital Statistics	Thomas J. Duffield

Those desiring detailed information should apply to the Massachusetts Department of Public Health, State House, Boston.

THE FOUNDATION PRIZE

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces that the annual Foundation Prize for this year will be \$150. Those eligible include only interns, residents or graduate students in obstetrics, gynecology or abdominal surgery and physicians who are actively practicing or teaching obstetrics, gynecology or abdominal surgery.

Competing manuscripts must be presented in triplicate under a nom de plume to the secretary of the association before June 1, be limited to 5000 words and such illustrations as are necessary for a clear exposition of the thesis and be typewritten (double-spaced) on one side of the sheet, with ample margins.

The successful thesis must be presented at the next annual meeting of the association, without expense to the association and in conformity with its regulations.

For further details, address Dr. James R. Bloss, *Secretary*, 418 Eleventh Street, Huntington, West Virginia.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, MARCH 23

MONDAY, MARCH 24

- *11:30 a.m. Carney Hospital. Monthly clinical meeting and luncheon.
- 12:15-1:15 p.m. Clinicopathological conference. Peter Bent Brigham Hospital amphitheater.
- *8:15 p.m. New England Heart Association. Boston City Hospital, pathological amphitheater.

- *8:15 p.m. The Role of Art in the Development of the Natural Sciences in the Renaissance. Professor J. Walter Wilson. Boston Medical History Club. Boston Medical Library, 8 Fenway.

TUESDAY, MARCH 25

- *9-10 a.m. Handwriting in Neurology and Psychiatry. Dr. J. C. Loring. Joseph H. Pratt Diagnostic Hospital.
- 12:15-1:15 p.m. Clinicoroentgenologic conference. Peter Bent Brigham Hospital amphitheater.
- 5 p.m. Massachusetts General Hospital. Hospital Research Council. Ether Dome.

WEDNESDAY, MARCH 26

- *9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
- *12 m. Clinicoroentgenologic conference. Children's Hospital.
- 7 p.m. Tufts College Medical School Alumni Association. Hotel Somerset, Boston.

THURSDAY, MARCH 27

- *8:30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital.
- *9-10 a.m. Syringomyelia. Dr. H. H. Merriitt. Joseph H. Pratt Diagnostic Hospital.
- 12:30 p.m. Community Nursing Council of Boston, Perkins H. Women's Educational and Industrial Union, 264 Boylston Street, Boston.

FRIDAY, MARCH 28

- *9-10 a.m. Some of the Medical Aspects of the Care of Patients with Rheumatic Fever and Rheumatic Heart Disease. Dr. T. D. Jones. Joseph H. Pratt Diagnostic Hospital.
- 8 p.m. Massachusetts Psychiatric Society. Massachusetts General Hospital.
- *8:15 p.m. A Discussion of Certain Splenopathies in Relation to the Vascular Bed of the Spleen. Dr. Allen O. Whipple. Robert Dana Evans Memorial Lecture. Evans Auditorium, 78 East Convent Street, Boston.

SATURDAY, MARCH 29

- *9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*Open to the medical profession.

ACUTE CHOLECYSTITIS

ROBERT ZOLLINGER, MD *

BOSTON

A DIFFERENCE of opinion exists today in regard to the treatment of acute cholecystitis. Until a few years ago there was general agreement that a policy of delaying operation until the acute signs and symptoms of the disease had subsided gave the best results. But in recent years the question has been raised as to whether the traditional conservative policy of delay is actually safest and most satisfactory,¹ or whether acute cholecystitis should, like acute appendicitis, be treated with immediate or early operation.

Shortly after this argument began, the cases of acute cholecystitis treated in the Peter Bent Brigham Hospital over a period of twenty years were reviewed to determine the results obtained. It was found that there was no consistent lowering of the mortality rate, which was 107 per cent for the 235 cases treated surgically.² This mortality rate seemed too high, and not in keeping with the general improvement in the care of surgical patients during this period. Accordingly it was decided to vary from the uniform standard policy of delay to determine if possible in each case just when surgery was advisable, whether this appeared to be within a few hours of admission to the hospital in fulminating cases or after several days of conservative treatment.

Since that time each patient entering the hospital has been treated as an individual surgical problem after the following plan of treatment. Once the diagnosis of acute cholecystitis is made, immediate hospitalization is urged, regardless of how slight the signs and symptoms may be. This cannot be accomplished unless the family physician considers the diagnosis of acute cholecystitis, like that of acute appendicitis, mandatory for hospitalization. Hospitalization does not necessarily mean that immediate surgery will be carried out, but merely that general measures will be instituted in preparation for surgery at a favorable time. On admission to the hospital, immediate measures are taken to re-

lieve pain and to establish fluid balance by the intravenous route, the routine laboratory work is done and the extent and severity of the inflammatory process involving the gall bladder are estimated. Signs, symptoms and laboratory data are evaluated frequently. In severe cases, such determinations are made at night as well as during the day. Whether or not early operation is performed depends on the progress of the inflammatory process after such therapy has been instituted. Early operation is carried out if the inflammatory process in the right upper quadrant progresses, or if there are signs of general peritoneal irritation. Stereotyped management in the treatment of acute cholecystitis is unsatisfactory, because each patient is an individual surgical problem, and because the optimum time for operation varies with each case.

An analysis was made of 121 consecutive cases of acute cholecystitis treated by operation in the Peter Bent Brigham Hospital during the last five years to determine the patients' clinical response following the above outlined plan of treatment (Fig 1). Approximately one fourth of the patients entered the hospital either after the acute attack had subsided or in the terminal stages of an acute attack, Group A. A second group, B, slightly smaller, responded promptly to treatment, with a return of the temperature, white-cell count and physical findings to normal within forty-eight hours. This is the type of response that the clinician usually expects, but unfortunately one that does not always occur. About as many patients fell into Group C and had an exacerbation of symptoms after forty-eight hours of conservative treatment as were in Group B, which responded early. Since a clinician cannot foretell which patient will get worse under conservative treatment, this is a strong argument in favor of early hospitalization. The greatest number of patients fell into Group D and required more than three days for the temperature to subside and the signs of inflammation to abate. A few cases, less than 10

*Assistant professor of surgery, Harvard Medical School; surgeon, Peter Bent Brigham Hospital.

per cent, remained stationary, that is, the temperature, white-cell count and physical findings did not respond to conservative treatment in Group E. In such cases the clinician should be suspicious of acute suppurative cholecystitis, possibly with a localized extracholecystic abscess. The patients

deaths occurred in the last two groups, made up largely of the severe cases. It is apparent that not all cases of acute cholecystitis subside even under ideal treatment. The surgeon, therefore, must observe these patients with acute cholecystitis early and frequently to decide in each case the most suitable time for operation.

Although immediate hospitalization is urged once the diagnosis of acute cholecystitis has been made, regardless of how slight the symptoms may

FIGURE 1. Clinical Response to Hospitalization.

Group A: acute signs and symptoms already subsided by time of admission; Group B: acute signs and symptoms promptly subsided in forty-eight hours; Group C: early improvement for forty-eight hours, followed by exacerbation of signs and symptoms; Group D: acute signs and symptoms persisted three days or longer; Group E: acute signs and symptoms persisted without response to conservative treatment; Group F: acute signs and symptoms increased in severity under conservative treatment.

making up Group F presented a fulminating type of infection, with rapid progress of the disease, probably owing to an overwhelming infection. The mechanical and chemical factors do not play an important role in this group. Four of the five

FIGURE 2. Duration of Acute Symptoms before Hospital Admission.

appear to be, as a matter of fact only about one third of the 121 patients in this series were sent to the hospital promptly, so that in the majority of cases, even if it had been desired, operation within forty-eight hours of the onset of the acute attack would have been impossible (Fig. 2). In only 3 cases during the five-year period did it seem advisable to operate on the patient within twelve hours of the time of admission to the hospital (Fig 3). These patients were very ill, and the possibility of a perforated viscus could not be ruled out. In 12 cases operation was performed from twelve to twenty-four hours after admission; in 16, on the second hospital day. In other words, 25 per cent of the patients in the series were operated on within forty-eight hours of admission to the hospital. The remaining 75 per cent were hospitalized seventy-two or more hours before opera-

tion. These figures refer to the period of hospitalization only and bear no relation to the duration of acute symptoms. This important factor, the length of time elapsing from the onset of acute symptoms until operation, is shown graphically in Figure 4. Despite the fact that 25 per cent of the patients were operated on within forty-eight hours of admission, on the basis of time elapsing from the onset of acute symptoms until operation this figure is reduced to 7 per cent. The clinician who first sees the patient must urge hospitalization promptly, so that the surgeon may choose the most suitable time for operation.

The incidence and dangers of perforation have contributed to the differences of opinion in the treatment of acute cholecystitis, for it is recognized

FIGURE 3. Days of Hospitalization before Operation.

that, in general, perforation increases the mortality and that at times the clinician cannot tell which case may result in a perforation of the gall bladder.⁸ As a rule, persistent pain and an increasing leukocytosis with increasing local signs of inflammation or persistent symptomatology under treatment imply that the gall bladder has perforated. However, physical findings and laboratory data do not always give reliable information as to the extent of the pathologic process involving the gall bladder, and for this reason early hospitalization and frequent evaluation of the patient's progress are im-

perative to maintain a low mortality. Except in rare cases, the perforation is walled off by the omentum and adjacent tissue, making an extra-cholecystic abscess. Perforation occurred in 16, or 13 per cent, of the 121 cases under discussion,

FIGURE 4. Duration of Acute Symptoms from Onset until Operation.

with a mortality of 6 per cent (Table 1). In all but one case, a walled-off abscess resulted. The perforation is rarely free in the peritoneal cavity.

TABLE 1. Incidence of Perforation.

		days
Abscess about fundus	5	7
Abscess about ampulla	4	5
Abscess into liver	4	4
Perforation into intestine	2	2
Free perforation	1	1
Total	16*	

*Seven patients had no previous biliary symptoms

However, there was one case with a free perforation, wherein the omentum was attached to the site of a gastric resection, performed years before.

Postoperative complications were present in 25 patients, approximately 20 per cent of the entire group (Table 2). As would be expected in upper abdominal surgery, a large percentage of these were pulmonary complications, such as atelectasis, with

complications as the result of infection the second most frequent. Each case was evaluated carefully, and any deviation from the normal course, regardless of how slight, was regarded as a complication.

Infection and pulmonary embolus were the chief causes of death (Table 3). In addition to acute

TABLE 2. *Complications.*

COMPLICATION	NO. OF CASES
Pulmonary	13

Total ...	25

cholecystitis, there was in each case a second serious complication—a calculus located outside the gall bladder. A stone was either in the common or hepatic duct, or else had eroded through the gall bladder into the intestine.

The ages of the patients were fairly well distributed, so that the mortality was not high in those above the age of sixty-five; in fact there was only one death in the 21 patients over sixty-five years of age (Fig. 5). We believe that advanced age in itself does not contraindicate surgery in acute cholecystitis.⁴

By treating the patient with acute cholecystitis as an individual surgical problem and by depend-

*Verified by autopsy.

ing on the response to hospitalization to determine the optimum time for surgery, either early or late, we have been able to reduce the mortality rate during the last five years from the former percentage of 10.7 to 3.8, a difference of 6.9 per cent, which is more than twice its standard error and therefore of statistical importance (Table 4). The gall bladder was removed in 71 cases, with a mortality rate of a little over 1 per cent, which is only a fraction higher than that for chronic cholecystitis. In 40 cases, choledochostomy was combined with cholecystectomy, with a mortality rate of 5 per cent. It is most important for the surgeon to

remember that common-duct stones occur in association with acute cholecystitis, for many clinicians believe that a stone blocking the cystic duct more or less certifies the absence of a common-duct stone.

TABLE 4. *Surgical Treatment.*

Total	131	3.8

*Ten patients had subsequent operations.

We have found common-duct stones in 20 cases of acute cholecystitis, an incidence of 15 per cent, which is almost as high as that in the cases of

FIGURE 5. *Age Distribution.*

chronic inflammation. From the literature, it appears that the surgeons performing early operation routinely do not find so many common-duct stones.⁵ The high mortality associated with a second operation for exploring the common duct to remove the overlooked stone will in the long run, I believe, counterbalance the initial low mor-

tality The mortality rate for cholecystostomy was high (11 per cent), but this procedure was carried out in only the severest cases Cholecystostomy is a valuable method, and the surgeon should not hesitate to utilize it when he doubts the safety of cholecystectomy.⁶ Except in patients who are very poor risks, cholecystectomy follows cholecystostomy, either in the same period of hospitalization or within a few months

Improvements in the general care of surgical patients, such as attention to fluid balance, must receive due credit for reducing postoperative mortality in recent years However, individualization of the treatment of the patient with acute cholecystitis has played a considerable role in this lowered mortality and is perhaps more important than a strict adherence to a standard policy of treatment

SUMMARY

Immediate hospitalization should follow the diagnosis of acute cholecystitis

Each patient with acute cholecystitis is an individual surgical problem The optimum time for operation depends on the patient's response to preoperative treatment

A mortality rate of 38 per cent was obtained over a period of five years in the surgical treatment of 121 cases of acute cholecystitis

A common-duct stone is a frequent complication of acute cholecystitis, and occurred in 15 per cent of our cases

THE CAUSES OF INDIGESTION AND THEIR RECOGNITION*

T GRIER MILLER, M D †

PHILADELPHIA

THE words "indigestion" and "dyspepsia" suggest some disturbance in the chemical processes that food materials undergo in the gastrointestinal tract That, of course, was the original explanation for the symptoms that so frequently develop in relation to the intake of food, and it is still the explanation given by most of the laity Although it is now recognized that such chemical changes are of relatively minor importance, no more satisfactory term has been devised to indicate a syndrome that includes a subjective sensation of epigastric discomfort or pain, often related to meals, anorexia, gaseous eructations, regurgitations, nausea and vomiting, and sometimes headache, palpitations and general nervousness and weakness For lack of a better term, I shall therefore refer to this group of symptoms, which is obviously related to the stomach, as "indigestion"

The justification for recognizing the syndrome is not that it constitutes a diagnosis, for after all it is no more a diagnosis than hypertension, dyspepsia or jaundice is But just as each of those terms connotes a group of clinical phenomena, ex-

plainable on the basis of a disturbed function of the body, so indigestion designates a picture of disturbed gastric physiology The dysfunction is itself a manifestation of some more fundamental disorder of the body; the identification of that disorder constitutes the diagnosis

Irrespective of the diagnosis, the clinical manifestations of indigestion are probably always immediately dependent on a disturbance of the motor function of the stomach, rarely of the secretory function Distress or pain in the epigastrium is believed to be due to an increase in the tension of the stomach walls, which in turn may be incident to spasm, especially of the cardia, pylorus or proximal duodenum, to increased tone of its general musculature, to overfilling of the organ or to variations in the normal progression of its peristaltic waves Eructations, regurgitations, nausea and vomiting, even anorexia, are also believed to be the result of a motor disturbance of some kind, at times to an actual reversal of the peristaltic waves Thus though indigestion may have many and varied causes, it apparently always in itself represents a localized motor disturbance of the stomach Secretory alterations are today believed to be important chiefly because of their effects on the motor function of the stomach

*Read before the New England Postgraduate Assembly in Cambridge Massachusetts, November 13, 1940

†From the Gastro-Intestinal Section (Kelsey-Thomas Foundation) of the Medical Clinic, University of Pennsylvania Hospital

†Professor of Clinical Medicine, University of Pennsylvania School of Medicine

In searching for the ultimate causes of indigestion one must therefore consider the mechanisms that control the motor functions of the stomach. Like other muscular structures, its walls normally possess a certain degree of tonicity or of contractility, this phenomenon being, in part, intrinsic and, in part, dependent on the innervation of the organ by the autonomic nervous system. The same autonomic nerves that supply the gastric muscles also supply other parts of the digestive tract, the liver and the gall bladder, the pancreas and the genitourinary organs. This relation undoubtedly accounts for so-called "reflex disturbances" in the stomach secondary to disease in those organs. Also, since the autonomic nervous system has a center in the hypothalamus, one can understand how certain cerebral organic lesions, even emotional disturbances, may set up alterations in the functions of the stomach. One thinks of the vomiting in massive brain lesions, of the nausea and vomiting in seasickness and migraine, of the gagging that occurs in some people on viewing a revolting scene, of the aerophagia, belching, nausea and vomiting that not infrequently develop under great emotional strain, as in the presence of a serious accident or the death of a relative. I need not pursue the illustrations, except to point out that vague digestive disturbances often originate in prolonged and less critical emotional stress, as in domestic quarrels, business upsets and undue mental fatigue.

The motor functions of the stomach may also be disturbed as a result of the local circulatory alterations that occur in cardiac decompensation or from portal obstruction. Indigestion is often the first manifestation of a failing circulation, of cirrhosis of the liver or of portal thrombosis. It may, likewise, result from toxic substances, acting locally or on the central nervous system, as in uremia, drug poisonings and certain general infections, such as typhoid fever, pneumonia and especially scarlet fever and other childhood infections.

Finally, disturbed motor function occurs as a result of local gastric lesions: gastritis, ulcer, tumors, pressure from the outside or intrinsic cicatrices. These may act directly by producing spasm of the gastric musculature or organic obstruction, interfering with either the normal entrance or exit of the gastric contents.

It is customary to speak of the gastric dysfunction due to psychic or emotional disturbance as "nervous indigestion," a gastric neurosis or functional dyspepsia; as a matter of fact, however, relatively few cases of indigestion are caused by organic disease of the stomach, and it is equally fitting to regard the indigestion of appendicitis, of gall-bladder disease or of an organic brain or

spinal-cord lesion as 'functional'. Even the indigestion of carcinoma or ulcer of the stomach is mainly the result of associated functional abnormalities of the stomach, superimposed on some locally irritating or obstructive phenomenon. In all cases, therefore, one may think of indigestion as a functional disturbance—a local motor dysfunction of the stomach resulting from faulty impulses reaching it through the nervous system, from toxins reaching it through the mouth or through the blood stream or from some locally acting factor, such as congestion, overfilling of the lumen of the organ or the presence of an irritating or mechanically obstructive lesion.

In spite of this viewpoint regarding the mechanism of indigestion and in deference to custom, we have continued, in our gastrointestinal clinic, to group under the heading of "functional gastric disturbance" or "gastric neurosis," all cases that cannot be explained as the result of an organic disease of the gastrointestinal tract or its associated organs. Our analysis (Fig. 1) is based on

	NO CASES	PER CENT	PER CENT					
			4	8	12	16	20	24
GALL-BLADDER DISEASE	787	30.9						
DUODENAL ULCER	624	24.5

APPENDICITIS	60	2.4						
	2542	100						

FIGURE 1. *Incidence of the Commoner Gastrointestinal Lesions that Produce "Indigestion."*

2542 cases of indigestion, 17 per cent of which were found to be functional. It is to be remembered that in such a clinic the cases are selected; those with obvious cerebral lesions, cardiovascular or renal disease and general infections go elsewhere in the hospital. The functional group, therefore, consists largely of patients whose symptoms are nonorganic. In private practice the functional group, even on such a basis of classification, is, of course, much larger—usually over 50 per cent.

Most of the 17 per cent have resulted from psychic or emotional disturbance, from anxiety states, fears, domestic turmoil and maladjustments in general. They are sent by general practitioners, who often suspect the nature of the trouble but consider it important to eliminate organic disease. Surprisingly, the mere demonstration of the absence of such disease alone cures many patients. With others, when the facts can be secured and the situation rationalized, the symptoms disappear.

With still others, help must be sought from mental hygienists, but this number is small. One wonders if even psychiatrists realize how many of these cases are satisfactorily handled by the resourceful and intelligent family physician or internist.

I shall now consider those patients who develop the syndrome on the basis of organic disease in the gastrointestinal tract or its associated organs.

Figure 1 shows that the largest number, 31 per cent, of the patients were proved eventually to have gall bladder disease, with or without stone. This observation is of great importance because it suggests that the gall bladder should always be suspected in every case of indigestion and eliminated before other causes are seriously considered. A probable diagnosis of cholelithiasis can often be made on the basis of a characteristic history of biliary colic, especially when associated with local tenderness or jaundice, but often, even in the presence of stone, and commonly, when no stone is present, the symptoms are similar to those of any other type of gastric dysfunction, consisting chiefly of vague discomfort, eructations, regurgitations, sometimes nausea and even vomiting. In such cases one should not eliminate the possibility of gall bladder disease without obtaining both a biliary-drainage test and a cholecystogram. Sometimes one and sometimes the other may be negative, even in the presence of stone, but rarely will both tests give a negative result. Our experience with proved cases shows that by the use of one or the other test some abnormality may be demonstrated in more than 95 per cent and in an almost equal percentage of the cases without stones.

Duodenal ulcer is the next most frequent cause of indigestion—24 per cent in our series. Its diagnosis or elimination on the basis of the patient's history is more accurately determined, but even in dealing with ulcer one should never trust the history alone, no matter how clearly the pain is related to the intake of food, how clear-cut its relief by alkalies or what the general course of the disease. An exactly similar picture may be present in the absence of ulcer. Gastric analysis is of relatively little help, although the acid figures in duodenal ulcer are usually high. X-ray study is of maximal importance. The accuracy of the roentgen ray investigation in the diagnosis of ulcer, in good hands, is today probably 95 per cent, and in all questionable cases it should be employed.

The functional disturbances of the stomach come next in frequency, after gall-bladder disease and duodenal ulcer, and have been considered.

The group to which I refer in Figure 1 as "functional colonic disturbance" requires some explanation. This applies to functional disturbances of

the stomach (indigestion) caused by some abnormality primary in the terminal ileum or colon; the latter may be organic or functional. It thus includes indigestion dependent on constipation, irritable colon, colonic diarrheas as well as terminal ileitis, diverticulitis and tumors of the colon. Perhaps I should also include cases of appendicitis, which, in spite of their general frequency, are rare in a medical clinic. In any event, all these disturbances that lead to stasis in the colon and terminal ileum, whether by spasm or organic obstruction, often produce a delay in gastric evacuation, with eructations, regurgitations, nausea and frequently vomiting. Intubation studies have clearly shown the influence of the spastic terminal ileum on gastric motility. This disturbance in the motility of the stomach may be reflex from below through the autonomic nervous system, or it may result from some more inherent nervous or muscular mechanism. At the moment I am concerned with the mere fact of its occurrence and with its contribution to the etiology of indigestion.

Bowel disturbances must not, therefore be forgotten in searching for the cause of indigestion. They are to be found by a careful consideration of the history of the case, by physical examination, especially by digital examination of the rectum, by proctoscopy and by the barium enema. Many cases have gone unexplained for a long time because of failure to remember this possibility and to employ the proper diagnostic procedures.

Each of the organic diseases of the stomach itself—ulcer, carcinoma and gastritis—occurred in about 4 per cent of our total group. The diagnosis of gastric ulcer depends on the same clinical and laboratory data as that of duodenal ulcer. Gastric cancer, however, deserves special mention. It may give rise to only the vaguest symptoms, or to none, until all hope of cure has passed. Its early recognition, therefore, is so important that no case of indigestion—no matter how trivial and especially if it occurs in a person of middle age or beyond in whom the symptoms have developed without obvious cause—should fail to have adequate study. This should include gastric analysis, roentgenologic investigation and sometimes gastroscopy. The gastric analysis alone should never be relied on, since in our experience 20 per cent of the cases showed a normal or high free acid content. The roentgen study, however, is of great importance and usually reveals the nature of the lesion, or at least indicates the need for further close observation. In the uncertain cases, the gastroscope may be of the greatest help, this type constituting one of the chief indications for its use.

Chronic gastritis is of equal frequency with ulcer and carcinoma of the stomach. Gastroscoy is definitely indicated when gall-bladder disease, ulcer and cancer have been eliminated and no probable explanation for the indigestion exists, even when the roentgen-ray study is negative. The time has passed for diagnosing gastritis on the basis of an alcoholic history, achlorhydria and mucus in the gastric contents. None of these may be present, and yet a well-developed atrophic or hypertrophic gastritis, curable by intelligent therapy, may be demonstrable. Whether or not atrophic gastritis is the cause of carcinoma of the stomach or pernicious anemia, it frequently precedes the development of those diseases; its recognition is important, therefore, if only to keep the subject under observation for the development of the signs of one of those more serious diseases.

I have placed little emphasis on the type of indigestion, which I believe has been overstressed in the past and is overstressed in modern textbooks. One hears too much about the gaseous eructations and night pains of gall-bladder disease, the relation of food to pain in ulcer, the boring pain of cancer of the stomach. These are helpful items of history, but often they are misleading and should not be allowed to determine the final working diagnosis in any case. The ob-

servations on physical examinations are rarely of significance in this type of disease; when positive, however, they may be of great assistance. Mistakes on the basis of the history and the physical examination alone are too costly; roentgen-ray investigation, biliary drainage, proctoscopic and gastroscoy studies, in spite of their trouble and expense, are timesaving and cheaper in the end for the patient and the doctor. The results must, however, be interpreted by the physician in correlation with his other clinical observations.

SUMMARY

I have defined "indigestion" as a syndrome resulting from motor dysfunctions of the stomach, and have referred to its association not only with diseases of the stomach and intestines and their appendages, but also with various circulatory, toxic, psychic and emotional disturbances. I have also outlined the relative incidence of its commoner causes as encountered in the gastrointestinal clinic of a general hospital, and have emphasized the importance of a complete investigation of every patient with the syndrome, employing, in addition to a careful history and a thorough physical examination, all the available special diagnostic procedures.

AN UNUSUAL CASE OF SUBDURAL HEMATOMA*

JOHN T. B. CARMODY, MD†

WORCESTER, MASSACHUSETTS

CASE REPORT

IT HAS been an observation of increasing frequency that hematomas of the cerebral group, particularly subdural hematomas, may assume the characteristics of almost any cerebral lesion. Much has been written concerning post mortem findings in such cases, and it is indeed no rarity for the neurosurgeon to operate on a supposed brain tumor, only to discover a subdural hematoma. Fur-

A 38 year old man was admitted to the Worcester City Hospital on June 3, 1933, with the complaint of headaches and a swelling of the right eye of 5 days duration. A ray examination confirmed the impression of severe pansinusitis. Shortly after admission, a turbinectomy was performed, together with drainage of an orbital abscess. After a hospital stay of 47 days, the patient was finally discharged improved with a diagnosis of pansinusitis.

FIGURE 1 Encephalogram

The postero anterior view reveals an over the left cortex with the cortical markings present. There is little evidence of an over the right cortical surface. There is no shift of ventricular system from the mid line.

thermore, it is now a well-established fact that operative exploration is the one method of ruling out the possibility of subdural hematoma in suspected cases.

In a series of 57 cases of cerebral hematoma, analysis has shown that in the great majority the preoperative diagnosis has offered no unusual difficulty. There was, however, one exceptional case in this group, and owing to its decidedly unusual character, it has been considered worth while to present it in the form of a report.

The second admission occurred on August 28, 1933. During the interval of 2 months between admissions, the former symptoms returned. The patient complained of severe headaches and a low grade afternoon fever. For the first time he also noted cloudiness of vision in the right eye. Routine examination showed an edematous and slightly reddened area about the right orbit, with tenderness to palpation. There was some exophthalmos. There was blurring of the right disk. Lumbar puncture revealed a pressure of 280 mm. of water. Subsequently, operation was performed and the patient was found to have, in addition to the right frontal sinusitis, a right orbital abscess and an abscess involving the right frontal lobe of the brain. He was finally discharged free of symptoms on the 76th hospital day.

The patient was admitted on February 19, 1940 for the

third time. He stated that during the interval of 7 years he had been perfectly well until approximately 2 weeks previous to admission. The diet had been adequate, and alcohol had been used sparingly. There had been no history of trauma of any kind. The present illness was ushered in by a head cold associated with headache. On

with each spell. Physical examination showed a slightly dilated right pupil and beginning edema of the right optic disk. The peripheral reflexes of the left side were increased over those of the right. On the left there were positive Babinski and Hoffmann reactions. There was some left-sided ataxia. Lumbar puncture was performed, and the

FIGURE 4

This drawing shows the operative field through a right temporoparietal bone flap, with the subdural hematoma in situ. The lower portion of the clot has been removed exposing the cerebral cortex.

the day before admission, except for these complaints the patient appeared well, soon after retiring that evening however, he became very restless, and it was noted that his face twitched slightly on the left side. Gradually, he became stuporous and was sent to the hospital. In the emergency ward he experienced 3 successive violent Jacksonian seizures involving the left side. These attacks were characterized by beginning twitching of the left side of the face, rapidly spreading into the left arm and then into the left leg. The seizures tended to subside in the reverse order of progression. Cyanosis and dyspnea were marked

initial pressure was found to be 210 mm. The total protein content was 22 mg per 100 cc, with clear fluid. A ray examination of the skull revealed nothing unusual except the old operative defect of the right frontal sinus. Following the lumbar puncture, moderate limitation of fluids and medication, the attacks became less frequent and severe during the next few days. However, they recurred suddenly and approached the condition of status epilepticus. The spinal fluid pressure had risen to 260 mm, and the total protein to 40 mg. The diagnoses varied considerably, including brain tumor, recurring brain abscess and adhesive

arachnoiditis, with a question of cortical scarring. An air injection was performed to substantiate or to rule out an expanding lesion. The air films revealed no shift of the ventricular system. In the anteroposterior view, cortical markings were present on the left side, but on the right no air was visualized in the subarachnoid space. In other words, the x-ray films supported the diagnosis of chronic adhesive arachnoiditis, with cortical scarring involving the right side of the brain (Figs. 1 and 2).

A right-sided bone flap was turned down, and directly beneath the dura a large localized clot, approximately 2 cm. thick, was exposed (Fig. 3). The brain cortex directly underneath this clot was flattened and depressed. The arachnoid, when exposed after removal of the clot, was slightly thickened but not adherent, and did not have the gross appearance of chronic adhesive arachnoiditis (Fig. 4). Furthermore, no evidence of cortical scarring was noted on gross examination. The diagnosis was subdural hematoma.

The postoperative course was uneventful. The condition of status epilepticus was completely relieved, and the patient experienced no further seizures. He was finally discharged on the 17th postoperative day, without complications. Since discharge, the patient has been followed at regular intervals. The abnormal neurologic findings gradually disappeared. He has been working at his old job in a machine shop and has experienced no ill effects. His general condition at the present time is described in his own words as "never felt better."

This case raises several interesting points. The first is whether or not the underlying brain involvement due to abscess formation resulted in any delayed contributing influence in the development

of this subdural hematoma. It seems logical to assume that there was no relation. The interval of seven years of absolute freedom of symptoms is against any association between the two conditions. The second point revolves about the fact that, both preoperatively and postoperatively, the patient denied any history of injury. Therefore, the question is again raised whether in cases of this sort blows of such relative insignificance that they are ignored or forgotten are sufficient to result in subdural bleeding. Patients suffering from deficiency diseases and alcoholism appear to be susceptible to the formation of subdural hematomas, and in many the evidence of trauma may be totally lacking. In the case presented above there was no evidence of deficiency or alcoholism; hence, insignificant trauma, which is often underestimated as an etiologic factor, seems to have been a reasonable causative agent.

SUMMARY

From a series of 57 cases of cerebral hematoma, an unusual case of subdural hematoma with questionable etiology has been presented. The possible relation between brain abscess and such late complications has been mentioned, and the question of insignificant trauma as an etiologic factor has been raised.

27 Elm Street

A PHARMACOLOGIC AND CLINICAL RE-EVALUATION OF AMPHETAMINE (BENZEDRINE) SULFATE*

WILLIAM M. CAMERON, M.D.,[†] AND J. KASANIN, M.D.[‡]

SAN FRANCISCO

AMPHETAMINE (Benzedrine) has had a wide clinical application in recent years, but empirical enthusiasms have outraced and often ignored the experimental studies that might have tempered them. This extensive use of amphetamine has not generally been based on a commensurate pharmacologic knowledge of the drug and of the group of amines to which it is related. Consequently, many erroneous notions regarding the locus and mode of action of amphetamine are current. This is unfortunate because it tends to spread inaccurate conceptions of the role of the autonomic nervous system in the physiopathology of disease processes.

Amphetamine is often called "sympathomimetic"; this is a misconception. The term "sympathomimetic" is a descriptive one meaning the mimicking of the effects of the sympathetic branch of the autonomic nervous system, "without," as Barger and Dale¹ have said, "involving any theoretical preconception as to the meaning of that relation [of action to sympathetic innervation] or the precise mechanism of action." Amphetamine mimics these effects to some degree, but there are important qualitative as well as quantitative differences between the actions of amphetamine and those of a truly sympathomimetic drug, such as epinephrine. Epinephrine reproduces all the effects of direct sympathetic stimulation because it activates the specific sympathetic effector mechanisms, and for this reason it is called "sympathicotropic." This elucidation of a more "precise

*From the Department of Psychiatry, Mount Zion Hospital.

[†]Clinical Professor of Medicine (neuropsychiatry), Stanford University School of Medicine.

[‡]Service, Mount Zion Hospital, assistant clinical professor, University of California School of Medicine.

mechanism of action" is a development that has begun since the work of Barger and Dale, and is one that still remains incomplete. Amphetamine, however, is not sympathicotropic, and appears to act through direct stimulation of smooth muscle and in other ways than through specific sympathetic channels. Similar misconceptions arose during the early experimental studies with tyramine¹ and ephedrine.² A study of amphetamine should include a survey of the pharmacology of related sympathomimetic amines. These drugs may differ only slightly in their molecular configuration, and may nevertheless show considerable individuality in their actions; conversely, certain structural configurations determine important generic characteristics. Among these are certain toxic effects that must be watched for in the use of amphetamine, since all such effects have not yet been ruled out experimentally.

The stimulant effect of amphetamine on the central nervous system and its effective administration by mouth have probably promoted experimentation with the drug for other purposes. Yet its various peripheral actions appear to present no advantage over those of ephedrine and related compounds already in use. Indeed, when pressor, vasoconstrictor and other actions from amphetamine are sought, the central stimulant action confronts one as a serious disadvantage. Furthermore, it is a regrettable trend toward categorical thinking that forces some workers to class amphetamine as a sympathetic stimulant, and to equate it with epinephrine. Nor is its central stimulant action any evidence for general sympathetic stimulation, since the most typically sympathicotropic drugs do not possess this property.⁴

This paper presents a summary of the pharmacodynamics of amphetamine and related compounds, and considers chiefly the results of experiments on animals, since proper analyses can hardly be made with clinical material. The objectives of this survey are to establish some general correlations between molecular structure and action, as an aid in identifying the relation of amphetamine to the sympathomimetic amines; to aid in establishing more definite criteria of sympathicotropic action, and to stimulate a more critical attitude toward claims in this direction.

PHARMACODYNAMICS*

Amphetamine or phenylisopropylamine (dl-alpha phenyl beta amino propylamine) is usually employed in the form of the racemic sulfate, except as an inhalant, when the carbonate is used. It induces general systemic effects when taken by

mouth, inhalation or injection in doses of 25 to 10 mg. Its structural formula is as follows.

Epinephrine, the most potent of the sympathomimetic amines, is a typical sympathicotropic drug; its structural formula is as follows:

The structure of epinephrine meets the original criteria for optimal sympathomimetic activity postulated by Barger and Dale¹ and confirmed by many other workers.⁵⁻¹⁰ It should be noted that epinephrine contains the catechol nucleus

It is evident, however, that amphetamine departs from this optimal molecular configuration, and it will become clear that it does so at a sacrifice of its sympathomimetic effects, regardless of what other actions it may have acquired.

This assumed relation between structures and function may be checked by the classic experiments with ergotamine and cocaine,⁶ Tyramine,¹¹⁻¹³ ephedrine,^{6, 14-17} phenylethanolamine^{6, 18, 19} and amphetamine,^{6, 20-22} all closely related structurally, fail to give to these tests the responses typical of sympathicotropic drugs. Functionally, then, they are only pseudosympathomimetic, and do not resemble epinephrine in their mode of action. Since the phenyl group of amines differs from epinephrine in both structure and function, it is of considerable significance that the addition of hydroxyl

*At the request of the Editors this section is presented in a summary form on account of its specialized nature.

groups to the phenyl ring of amphetamine,^{22, 24} ephedrine^{9, 10} and phenylethylamine^{22, 24, 25} has in each case resulted in a sympathomimetic action more closely resembling that of epinephrine than was characteristic of the original drug. We may therefore conclude that the presence of the catechol nucleus, or possibly merely the meta OH-group, is necessary for sympathicotropic action. Variations in the side chain are of lesser significance. A longer side chain sacrifices intensity of action for greater duration, but carries greater toxicity. In the following summary of the effects of amphetamine on the various organ systems it would be well to bear in mind the comparison of these with the effects cited for other amines. If amphetamine seems neither more potent nor less toxic, it would be wise to advocate the use of one of the other amines.

Pressor Effects

Amphetamine has a pressor action in animals, although the effects are rather irregular and do not correspond closely to the dosage used.²⁰ Its ratio of activity to epinephrine is approximately that of 1:425,⁷ and it is consequently classed as a weak pressor agent. It is exceeded in activity by ephedrine, tyramine and many other amines. Tachyphylaxis is probably more marked than with ephedrine, and in some cases even a second injection was ineffective or caused a fall of arterial pressure.⁷ Its duration of effect is relatively prolonged.

The principal virtue of amphetamine in clinical use lies in its activity when given by mouth, in contrast to most of the other amines.^{26, 27} Propadrine (phenylpropanolamine), however, might be worth trying when there are indications for the oral administration of a pressor drug. It is probably more active than either ephedrine or amphetamine,⁷ is less toxic than ephedrine,²⁸ and because of its beta OH-group, is estimated to be one third as toxic as amphetamine.²⁷

Cardiac Effects

Thienes and his co-workers²⁰ found that the heart in atropinized animals responded to amphetamine with a moderate increase in rate. There was no significant change in stroke volume. Chen and Schmidt,³ Chen and Meek,^{14, 15} and others^{13, 29} have cited the depressant effect of ephedrine on the cardiac musculature. The possibility that amphetamine possesses similar undesirable effects must receive consideration. Chen and Meek¹⁴ made electrocardiographic studies of dogs and rabbits that received large doses of ephedrine and found depression of the conduction system and various degrees of heart block. This was followed by ventricular fibrillation in some cases. It

is significant that large doses of tyramine had no such effects. Phenylethanolamine is also relatively nontoxic to the heart.^{18, 19, 22} Since a short side chain and the presence of an OH-group lessen toxicity,^{22, 27, 28} a longer side chain, lacking an OH-group, has greater toxicity. Thus, the molecular structure of amphetamine conforms to the criteria for relatively high toxicity. Many workers^{8, 22, 30, 31} have demonstrated that amphetamine and other phenyl amines are of little value in experimental circulatory collapse, and that the catechol derivatives are most effective. Clinically, Waud³² has demonstrated cardiac depression in healthy young subjects following extremely large doses of amphetamine. Other workers have reported paradoxical falls in blood pressure during ordinary clinical use of the drug,³³⁻³⁵ but few alarming cardiovascular effects have been cited.³⁵

Bronchial Action

Clinicians have long been interested in finding an antiasthmatic substitute for ephedrine that could be effectively administered by mouth and would dilate the bronchi as well as ephedrine without the undesirable cerebral stimulation. Since amphetamine fails in the former condition, and exceeds ephedrine in the latter³⁷ it cannot be seriously considered as a bronchial dilator. Epinephrine and the other catechol derivatives far exceed amphetamine, ephedrine, tyramine and their structurally related amines in bronchodilator action.^{8, 38-42}

Effects on Smooth Muscle

Both epinephrine and ephedrine inhibit intestinal motility. Chen, Wu and Henriksen²⁸ reported that the majority of twenty-four phenylring derivatives, tested on isolated rabbit intestine, did likewise. Experiments with amphetamine have been less clear cut; Thienes and co-workers²⁰ have been unable to arrive at a formulation of the mode of action of amphetamine, although they have shown in nerve-degeneration experiments on the cat intestine that the modes of operation of amphetamine and ephedrine differ qualitatively from that of epinephrine.²¹ Alles and Piness²³ obtained increased tonus with minimal concentrations of amphetamine, and relaxation with greater concentrations on the isolated rabbit ileum.

Myerson and Ritvo¹³ believe that amphetamine is of decided value in relaxing gastrointestinal spasm of intrinsic or reflex origin, and that this relaxation occurs without a concomitant delay in gastric emptying time. Rosenberg, Arens, Marcus and Necheles,⁴⁴ however, obtained inconclusive clinical results with amphetamine, and in experimental studies found that the drug often induced

gastrointestinal spasm rather than relaxation. The conclusions of Beyer and Meek⁴⁵ also differed from those of Myerson and Ritvo; they found that amphetamine caused a delay in the final emptying time of the stomach, but that this effect was feeble as compared with that of atropine or ephedrine.

Mydriatic Action

Mydriasis may be produced by epinephrine, ephedrine, tyramine, amphetamine and many other amines.^{3,13,19,46} There appears to be nothing unique in the clinical effects of amphetamine when used as a mydriatic, but denervation experiments clearly demonstrate that it is not sympathicotropic in action.^{19,21} Caution should therefore be observed in drawing conclusions concerning physiologic pathology on a basis of its clinical effects.

Effects on Blood Sugar

Among the aromatic amines only epinephrine and related catechol derivatives possess the capacity to induce a rise in the blood sugar level in nontoxic doses. Schaumann² has shown that the introduction of two OH groups into the benzene ring—giving ephedrine a catechol nucleus—is enough to bestow the capacity to raise the blood sugar. Conversely, this highly specific sympathicotropic effect is lacking in drugs that have deviated as far as amphetamine from the molecular structure of epinephrine.^{23,47,48}

Tachyphylaxis and Toxicity

Tachyphylaxis is that phenomenon in which a drug elicits progressively weaker responses in a succession of injections, although there is no apparent general physiologic decline to explain the fact. Pressor responses may even be reversed to depressor ones, and this may occur within three or four injections. Chen and Schmidt³ described this phenomenon in their early work with ephedrine. It is common to most ephedrine derivatives, is present with phenylethylamine,²² and is marked with amphetamine.⁷ Tachyphylaxis does not occur with epinephrine and related catechol derivatives or with tyramine and phenylethanolamine.

It is evident that there is a close relation of structure to this important feature of drug activity. Amines that have long side chains and lack the OH group, like amphetamine, show tachyphylaxis in its most marked degree. These structural features are also characteristic of the more toxic amines.

Chen and Schmidt³ assumed that tachyphylaxis was caused by the cardiodepressant action of ephedrine, although the heart seemed quite responsive to subsequent injections of epinephrine. But Tainter,⁴⁹ using Gibbs's artificial heart in cats,

demonstrated typical tachyphylaxis after ephedrine, proving that it was not entirely dependent on an altered response of the heart.

The most prevalent hypothesis seeking to explain the relation of tachyphylaxis to the structure of compounds like amphetamine and ephedrine is that these more stable compounds are not readily oxidized by the organism, and that consequently local fatigue occurs at their locus of operation, since they remain in the tissues until excreted by the kidneys. Since epinephrine operates on a different locus, it is still effective when the organism is fatigued by the action of these drugs. This failure to be quickly metabolized possibly explains their effectiveness when taken by mouth^{26,27} and their generally more toxic nature, and is compatible with the more prolonged action of drugs like amphetamine.

Toxicity is best stated in terms of "therapeutic index" or ratio of toxic to therapeutic dose. The present study has shown that this index diminishes with the increasing length of the side chain and with the depletion of the amine of its OH groups. The substitution of a propylamino group for the methylimino group in ephedrine, for example, results in the drug's manifesting only depressive and toxic effects.²³ It is evident from a consideration of its structure that amphetamine must be suspected of considerable toxic effect and a relatively low therapeutic index. The experimental studies cited have supported this conclusion. The use of repeated doses of amphetamine may lead to cumulative toxic effects, since the drug is not readily oxidized and is only slowly excreted through the kidneys.⁵⁰

In many of the present applications of amphetamine, the central stimulation is a highly undesirable side action. In this respect the use of the drug for its feeble gastrointestinal effects is illogical, since its central stimulant action surpasses that of more effective drugs. It is not yet possible to say that in clinical doses amphetamine has no injurious effect on the heart. The collapse and death of a college student, recently reported by Smith,⁵¹ suggest that accumulation may be a significant factor even when small doses are taken. The majority of cases of severe toxic reactions have occurred following no more than the therapeutic dose, and it is apparent that these patients were unusually sensitive to the drug. Nevertheless, since the widespread clinical use of amphetamine cannot be justified—except in certain conditions mentioned below—by the pharmacologic findings, it is unwise to risk even a remote chance of a grave toxic reaction.

Critique of Clinical Applications

A complete review of the present status of amphetamine therapy will not be presented, since this has been done recently by Davidoff and Reifenshtein^{53, 52} and others.⁵³⁻⁵⁵ There is little doubt that the central effects of the drug have been very beneficial in narcolepsy,^{37, 56, 57} in postencephalitic parkinsonism,^{58, 59-60} and in alcoholic, barbiturate and some other intoxications.^{52, 61} But its use in the psychotic states has not on the whole been encouraging.^{34, 62-65} There has been little modification of the essential features of the schizophrenic or depressive reactions in cases treated with amphetamine. Occasionally patients appear more talkative and accessible, but these minor responses are just about balanced by panicky reactions and suicidal attempts in other patients. Wilbur, MacLean and Allen⁵³ obtained considerable but passing improvement in patients with so-called "chronic exhaustion" or mild depressive states. It is questionable whether one can consider this experience a specific response to amphetamine in any way analogous to the well-maintained responses in the patients with medical disorders.^{37, 57} Non-specific factors are difficult to control. Bahnsen, Jacobsen and Thesleff,⁶⁶ for example, found that of 100 normal adults comprising a control group in experiments with amphetamine, 13 per cent had lessened fatigue following the use of starch tablets.

Guttman and Sargent⁶⁴ point out that amphetamine tends to exaggerate the innate personality trend, and may exaggerate hypochondriacal or obsessive reactions. They, and others,⁵³ have avoided its use in anxiety states, which tend to be heightened by the drug. Anxiety is a common component of many neuroses. One should consequently expect superficially satisfactory responses—decreased awareness of fatigue, talkativeness and mild hypomanic euphoria—to overlay a concomitant state of increased tension, potentially capable of involuntary and unintegrated expression. Panic states do occur, of course, and constitute an eventuality demanding constant vigilance in the use of amphetamine in the major reaction types. We are inclined to regard many of the disagreeable symptoms—palpitation, sweating and tremor—elicited by small doses in some normal subjects as manifestations of central rather than peripheral action, a central action that, in effect, mobilizes latent anxiety. Bahnsen et al.⁶⁶ also ascribed several of the peripheral effects of amphetamine to stimulation of the central nervous system.

Because negative findings are less apt to be reported than positive ones, we submit the following report. One of us (J. K.) has employed amphetamine* rather extensively in the psychiatric clinics

of the Michael Reese Hospital in Chicago and of the Mount Zion Hospital in San Francisco, and can only conclude that the drug appeared to be of questionable value in the treatment of patients with psychogenic disorders. The conspicuous absence of either subjective or objective responses to doses of 10 to 20 mg. was quite common among these patients. Seventy-five patients, 36 men and 39 women, were so treated. Most of them were referred to the psychiatric clinics from other clinics of these hospitals, where they were complaining of nervousness, and where the functional nature of their symptoms became apparent to the examining physicians. Ten patients suffered from varying degrees of depression, whereas 65 showed symptoms of tension, insomnia, various somatic complaints with varying degree of anxiety, a feeling of insecurity, loss of faith in themselves, premonitions of dangers and death, and marked dependence on their physicians.

In the cases of depression, 3 patients showed a slight transitory improvement, but even then it was not possible to rule out other factors that might have been equally responsible for the improvement. The 3 patients who improved stated that amphetamine was responsible for giving them some "pep" to get up in the morning when they would otherwise prefer to stay in bed. It must be remembered, however, that together with the command to take the drug, the patients were told that they would feel very much better. Five patients reported no improvement, and 2 became definitely worse, complaining of feeling unnatural, giddy and "funny in the head," and getting more discouraged.

In the 65 patients suffering from neuroses, the suggestion that the drug would be very effective in ameliorating symptoms was used in 30, but only 9 stated that they felt better. Here one met with most paradoxical observations: 2 patients said that after taking amphetamine at night (by mistake) they slept very much better, and they asked that the drug be substituted for phenobarbital. Three patients said that they felt better and had more ambition than previously, but this lasted only a few weeks, after which they again became quite neurotic and complained of their previous symptoms. Four patients left the clinic, stating that they felt better, and did not respond to a follow-up letter. In the 35 cases in which the drug was given and no suggestion in any form was used, the patients reported no change. These patients were in the clinic for several months, were more or less stationary in their symptoms, and showed no response to various sedatives. It is quite possible that new patients who are given amphetamine at their first visit to the psychiatrist appear to re-

*Supplied through the courtesy of Smith, Kline and French Laboratories, Philadelphia.

act more favorably to the drug, but one must discount the effect of psychotherapy and not confuse it with the specific effect of the drug.

In general, in the light of our critical observations, there seemed to be no special indication for the use of amphetamine in either psycho-neuroses or depressions. This was in marked contrast with the 2 cases of narcolepsy, in which a very dramatic improvement was similar to that reported by Prinzmetal³⁷ and Ulrich.⁵⁸ Dr. George S. Johnson,⁶⁷ director of the Psychiatric Department of Stanford University Hospitals, has informed us that in his clinic the experience with amphetamine was similar to our own.

SUMMARY

The molecular configuration of amphetamine (Benzedrine) places it in the group of phenyl amines, another member of which is ephedrine. None of the phenyl amines are truly sympathomimetic in their effects.

Amphetamine is not sympathicotropic in its mode and locus of operation, and consequently should not be equated with epinephrine.

Amphetamine is relatively feeble in potency in comparison with other aromatic amines, such as epinephrine, arterenol and tyramine.

It is clearly established that increased length of the side chain and the absence of OH-groups are associated with increased toxicity. By these criteria amphetamine must be suspected of relatively high toxicity, which can be ruled out only by further pharmacologic experimentation.

Because the toxicity of amphetamine has not been sufficiently determined and its action is relatively feeble, it seems preferable to employ other amines for peripheral effects on the cardiovascular, gastrointestinal and other systems.

Clinically, amphetamine is valuable in certain diseases of the central nervous system, such as narcolepsy and postencephalitic parkinsonism, and in certain intoxications. The administration of the drug in neuroses, depressions and schizophrenia seems of doubtful value, and may occasionally be harmful.

Favorable results reported in such heterogeneous states as orthostatic hypotension, chronic alcoholism, obesity and schizophrenia do not speak for specificity of action, but indicate rather that other variables (present in every therapeutic situation) may have contributed to the ultimate improvement of the patients.

ENCEPHALOPATHY FOLLOWING NEOARSPHENAMINE THERAPY*

EPHRAIM ROSEMAN, M.D.,† AND CHARLES D. ARING, M.D.‡

CINCINNATI

THE occurrence of central-nervous-system reactions following the intravenous administration of the arsphenamines is infrequent, and the clinical and pathological pictures of these catastrophic states have not become clear to the physician. Smith and Newbill¹ in 1939 found 175 cases of arsenical encephalitis in the literature. Glaser, Imerman and Imerman² in 1935 made an exhaustive study of the literature to determine the frequency of so-called "hemorrhagic encephalitis and myelitis" secondary to intravenous arsphenamines. These authors collected 146 cases of encephalitis, 8 of myelitis and 4 of encephalomyelitis from a group of 191,125 patients who had received 1,108,778 injections of the arsphenamine compounds. The incidence of death due to central-nervous-system involvement was 1 in every 5398 cases, or 1 in every 28,768 injections. The mortality rate of patients suffering from arsphenamine encephalitis was 76 per cent. Glaser, Imerman and Imerman pointed out that these reactions occur also in non-syphilitic cases and are apparently unrelated to the age and sex of the patient, to the quantity of

the drug administered, to the number of injections given, or to the toxicity of the drug.

Toxic reactions in the central nervous system occur most commonly after the second dose (50 per cent in the series of Glaser, Imerman and Imerman), and usually develop from twelve to one hundred and forty-four hours after the injection. It has been noted² that only 0.5 per cent of the reactions occurred between the ninth and fifteenth injections.

We are reporting the clinical and pathological findings in a case of encephalopathy that occurred after the fifteenth intravenous injection of neoarsphenamine. This late reaction is quite unusual and merits consideration. The pathological picture presented differs somewhat from that characteristically described as "hemorrhagic encephalitis" following arsphenamine.

CASE REPORT

E. B., a 27-year-old married Negress, had been treated in various clinics of the outpatient department of the Cincinnati General Hospital since January 11, 1939, for many unrelated complaints, including vaginal bleeding, inability to become pregnant, tumor of the breast (a fibroadenoma was subsequently removed) and an infected dog-bite wound of the hand. Otherwise the general physical and neurologic status had been normal. On April 25, 1939, a blood Wassermann reaction was positive, although tests performed 1 year and also 1 month pre-

*Work aided by a grant from the Charles E. Fleischmann Endowment From the Laboratory of Neuropathology, Cincinnati General Hospital, and the Department of Internal Medicine (Neurology), University of Cincinnati College of Medicine

†Fellow in neurology, Cincinnati General Hospital.

‡Attending neurologist, Cincinnati General Hospital; assistant professor of neurology, University of Cincinnati College of Medicine

viously in other hospitals had given negative reactions. Another serologic blood test, done on June 1, 1939, confirmed the positive result. On this basis, antsyphilitic therapy was begun. From June 19 to August 28, the patient received ten weekly intramuscular injections of bismuth (2 cc of bismuth subsalicylate in oil). From September 1 to November 17 neosphenamine was administered intravenously at weekly intervals, each dose containing 0.6 gm. Another course of weekly injections of bismuth was then given from November 20 to January 22, 1940. From January 26 to February 23 neosphenamine was given weekly—0.6 gm to the dose. Thus by February 23, the patient had received the fifteenth injection of the arsenical.

On February 27, the patient was admitted to the hospital in a comatose state. An inadequate history was obtained from the employer. The patient had been in good health until noon on February 25, when she complained of slight headache and dizziness. She was unable to perform her duties as a housemaid. Later that day the headache became intense, and she went to bed. On the morning of February 27, she became delirious, and gradually lapsed into coma. She was then brought to the hospital.

The patient was unconscious, breathed stertorously, and was obviously seriously ill. General physical examination revealed a well nourished and well developed colored woman with a warm, dry skin and a generalized, mild lymphadenopathy. Examination of the heart, lungs, abdomen and extremities was essentially negative, and there was no cutaneous abnormality.

The obviously important findings were confined to the nervous system. The pupils measured 6 mm in diameter and were equal in size and regular in outline. They dilated widely when a flashlight was shone into them, and then slowly contracted through a small range, despite the maintained light. The eyes tended to wander to the left but were quickly jerked back to the mid line with coarse, nystagmoid movements. The optic fundi were normal. There was, at times, increased resistance to passive movements of all the muscles of the trunk and extremities. These periods were marked by tonic extension or spasm, which lasted from 15 to 20 seconds. Following these episodes, muscular tone became notably decreased, and the respirations became slow and shallow. There was no spontaneous purposeful movement. The only response to painful stimuli occurred on severe supra-orbital pressure, which caused the patient to grimace slightly. The tendon reflexes in the arms and legs were hyperactive bilaterally. The Hoffmann sign was strongly positive on both sides, and the plantar responses were flexor bilaterally. No abdominal reflexes were obtained. There was mild stiffness of the neck, but no Kernig or Brudzinski signs were elicited.

The course was steadily downhill. On the day following admission, the periodic tonic extensor spasm had disappeared. Muscular resistance and the tendon reflexes were normal and equal in all the extremities. However, Cheyne-Stokes respiration appeared, and death ensued in the early morning of February 29.

The temperature varied from 99.4 on admission to 100.8° F terminally. The pulse rate ranged from 86 to 120, and the respirations from 22 to 36 per minute.

A lumbar puncture performed on admission revealed an initial pressure of 300 mm of water. The cerebrospinal fluid was clear and colorless and contained 1 lymphocyte and 3 red blood cells per cubic millimeter. The Pandy reaction was +, +, +, and the total protein 205 mg per 100 cc. The cerebrospinal fluid Wassermann re-

action and gold sol curve were negative. At a second lumbar puncture the following day a cerebrospinal fluid pressure of 200 mm. was demonstrated. The fluid was clear and colorless, and contained no white cells and 8 red blood cells. The Pandy reaction was +, a quantitative protein determination was not done on this fluid.

The red cell count was 3,910,000, and the white cell count 5000. The differential picture was normal, and the hemoglobin 12.2 gm. The urine was normal.

Autopsy. The pathological findings exclusive of those in the nervous system were confluent lobular pneumonia with acute fibrinous pleuritis, acute bronchitis, left ventricular hypertrophy, severe toxic hepatitis and focal necrosis of the liver, acute splenitis, toxic nephrosis, early atherosclerosis of the aorta, mild pleural fibrosis, cystic right ovary, intracranial fibroadenoma of the breast, and leiomyoma of the uterus.

The right lung weighed 600 g, the left 275 g. The right middle and lower lobes were swollen, and varied in consistence from a subcapitate state to complete loss of crepitus. The lowermost portion of the middle lobe and the entire lower lobe on the right were dark red, mottled and irregularly friable on section. The remainder of the right lung and the entire left lung were normal, except for moderate congestion of the dependent portions of the latter. A section of the right lower lobe was removed with sterile precautions, and no pneumococcus could be identified from this material in the laboratory. Microscopic examination of tissue from the involved lobes confirmed the diagnosis of confluent lobular pneumonia. There were some signs of aspiration. All the evidence indicated that the pneumonia was of the hypostatic or terminal type.

Examination of the nervous system was limited to the brain, which weighed 1325 g. The convolutions were moderately flattened and broadened and the vessels of the meninges were congested. There was herniation of the uncus of the temporal lobe on both sides, more marked on the left. There was a well defined cerebellar pressure cone, which, although small, was sharply indented, particularly on the left side. The vessels of the circle of Willis were soft, and the circle was of normal configuration.

The most notable feature of the sectioned brain was the presence throughout the white matter of discrete or confluent bright red, pinpoint lesions, resembling petechiae. The tendency to symmetrical involvement of both hemispheres was striking (Fig 1). Macroscopically it was noted that the gray matter of the convolutions and basal ganglia was not involved. The morbid process was widespread extending from the frontal to the occipital poles, and it spared none of the lobes. However, the internal capsule and the corpus callosum were more extensively involved than other structures. The sectioned brain stem and cerebellum revealed only a few scattered petechiae in the cerebellar brain.

Microscopically, the brain lesions consist of widespread and multiple foci of perivascular softening and demyelination. These are disseminated throughout the cerebral hemispheres, but are not found in the brain stem. These foci are present only in the white matter. In the center of the lesion there is a capillary or precapillary vessel with markedly swollen or completely destroyed endothelium. Immediately surrounding the central vessel there is an area of necrosis, which is relatively acellular, but in which a few macrophages with ingested pigment are noted. Pigment also lies free in these foci, and there are a few oligodendroglia and astrocytes in the perivascular spaces. Of course, these areas are denuded of myelin.

Surrounding these regions of necrosis is an occasional collar of neuroglia, composed of oligodendroglia and astrocytes. Only an occasional, recent, perivascular hemorrhage is seen in the subcortical white matter, internal capsule, corpus callosum and anterior commissure.

Vascular changes are widespread, and involve both gray and white matter, although they are more marked

reaction, but the vessels are moderately congested. There is no histological evidence of syphilis.

It has been suggested that this type of lesion in the nervous system may be associated with acute infection, and cases have been reported to support this thesis. Pneumonia was found at autopsy

FIGURE 1.

Note the discrete, pinpoint and confluent lesions resembling petechiae, limited macroscopically to the white matter. The cerebrum was sectioned vertically into blocks 1.5 cm. thick. The position of the first block has been reversed to show the anterior extent of the process in the frontal poles. The corpus callosum was sectioned at autopsy to allow for better penetration of the formalin solution.

in the latter. The endothelium of some of the capillaries is hypertrophied so that, at times, the lumina are completely obliterated. Occasionally a thick hyaline thrombus completely occludes the lumen.

The changes in the nerve cells of the hemispheres and the brain stem are widespread and consist chiefly of moderate to severe chromatolysis. There is some glial proliferation. The leptomeninges contain no inflammatory

in this case, but the mildness of the infection clinically and pathologically seems to indicate that the encephalopathy was not based on this infection. There were no signs of pneumonia before death. The rectal temperature did not go above 100.8°F., and the white-cell count fifty-two hours after the onset and thirty-six hours before death was

5000 Neither of these facts points to infection. The clinical signs were those of an overwhelming neurologic catastrophe that resulted in death eighty-eight hours after the initial symptom of slight headache. Nevertheless, the possibility that an acute infection was responsible for the encephalopathy in this case cannot be discarded.

The findings in this case deviated somewhat from the usual clinical and pathological descriptions of so called "arsphenamine encephalitis." The unusual feature was the onset forty eight hours after the fifteenth intravenous injection of neoarsphenamine. So far as we have been able to determine, there has been no authenticated case in which the disease occurred so late. As pointed out by Glaser, Imerman and Imerman,² Alpers,³ and Russell,⁴ the late occurrence of encephalopathy strongly suggests the possibility of sensitization of the cerebrovascular tree as the pathogenetic element, rather than the toxicity of arsenic per se, if this element is responsible.

The important pathological point was the occurrence of focal perivascular demyelinated areas of necrosis, widely distributed throughout the white matter of the cerebral hemispheres and largely unassociated with petechial hemorrhages. Russell⁴ has pointed out that the necrotic foci do not represent a later stage of hemorrhage, but that the two processes, hemorrhage and perivascular necrosis, are quite independent of each other.

Thus, the cognomens "brain purpura" and "hemorrhagic encephalitis" are in reality misnomers, for the hemorrhagic phenomena may play but a minor role. The blood-vessel changes were marked in this case, and were noted in the gray and white matter.

SUMMARY

A fatal case of encephalopathy that occurred forty-eight hours after the fifteenth intravenous injection of neoarsphenamine is recorded. Confluent lobular pneumonia and toxic changes in the viscera were found at autopsy, in addition to the lesions in the nervous system. The most important lesions in the nervous system were focal perivascular areas of necrosis unrelated to hemorrhage. The perivascular necrosis was in relation to changes in the small blood vessels, chiefly of the endothelium, which not infrequently occluded the vessel. Petechial hemorrhages, which occurred probably simultaneously but apart from the perivascular necrosis, did not seem to be important in the analysis of the lesions of the disease.

MEDICAL PROGRESS

TUBERCULOSIS

DONALD S. KING, M.D.*

BROOKLINE, MASSACHUSETTS

DR. HENRY D. CHADWICK,¹ in his 1940 address as president of the National Tuberculosis Association, estimated that if the average decline of the last two decades can be maintained, the death rate from pulmonary tuberculosis in the United States will be 32 in 1950, 21 in 1960, 14 in 1970, 9 or 10 in 1980, and that "the bells that ring in the year 2000 may sound the death knell of the tubercle bacillus." In weight reduction, however, it is the last pounds that are the hardest to take off, and perhaps one should not expect to the last a steady decline in the death rate. In the meantime, there are wars and rumors of wars that may upset all calculations. It is therefore natural in this review to turn to the relation of tuberculosis to war, and since at present the United States is not fighting but assembling an army, the first problem concerns the detection of tuberculosis in the recruits for that army. Such a study outlines present methods of the diagnosis and control of tuberculosis.

TUBERCULOSIS AND THE UNITED STATES ARMY

As the United States begins its second draft of manpower in less than twenty-five years, one is appalled at the large number of patients with active or potentially active tuberculosis that were taken into the service in the draft of 1917, and the drain on the financial resources of the country that these cases have since become. The problem is very clearly stated by Spillman,² whose article is the source for the facts in the following four paragraphs.

The inadequacy of physical examination. It is difficult to realize how great a change has taken place in the diagnosis of pulmonary tuberculosis in the last twenty years. In 1917 the final criterion for determining the existence of active pulmonary tuberculosis was the presence of persistent post-tussal moist rales. This rule was adopted by the Army Medical Department on what it considered the best authority of the day. It is true that even at that time a few roentgenologists, particularly Dr. Lewis G. Cole, tried to induce the Surgeon General to make the roentgenogram and not physical signs the decisive factor in diagnosis; but the difficulty in obtaining enough imported

glass plates, the cost of photography and the lack of trained roentgenologists seemed insuperable obstacles. Since then it has been proved that if one does rely on the discovery of rales, seven eighths of the early active lesions, as shown in the x-ray film, will be missed. Cole made a start in the collection of evidence of the superiority of x-ray diagnosis when in 1917 and 1918 he found that of 19 cases without physical signs but with x-ray evidence of pulmonary tuberculosis, at least 8 became heavy compensation liabilities because of the development of active processes.

The blame for many of the cases of tuberculosis taken into the Army cannot be placed, therefore, on the examining physicians but on the method of examination then in vogue. Nevertheless, one reads with surprise, that there were "... enormous numbers of health seekers whom the boards of the first draft sent, thinking that change of climate might benefit the manifestly tuberculous. . . ." This was obviously unfair to the Government and to the healthy comrades thus exposed to the disease, although it must be admitted that the danger of exposure in adult life was not appreciated then as it is now.

The cost of missed cases. In 1922, 36,600 soldiers received compensation for tuberculosis, and in 1939, 55,634, including 1947 deaths for that year. The approximate cost to the Government from 1917 to 1941 is as follows:

Cost of vocational training	\$129,000,000
Insurance	130,000,000
Compensation	600,000,000
Hospital care	100,000,000
Total	\$959,000,000

This does not include the cost of hospital construction. And Spillman points out an additional fact:

Every month that goes by sees approximately three million dollars for compensation added to this bill. . . . It becomes a nice problem in accounting to estimate, from the foregoing data, just how much it costs to take a man into the service when he has tuberculosis. . . . I make it out somewhere around \$10,000 per man to date, certainly not less than \$7500, a figure to which can be added at least \$50 a month for the rest of the

*Associate in medicine, Harvard Medical School; associate physician, Massachusetts General Hospital; consultant, Middlesex County Sanatorium.

man's life and compensation benefits for his dependents after his death

The use of the x ray in the present draft Obviously no man with tuberculosis should be taken into the service, and the way to detect the disease is to x-ray the chests of all volunteers and draftees. Fortunately, such study is rapidly becoming part of the routine examination for admission to the Army. How many applicants will be rejected is not yet known, although the preliminary unofficial figures for Massachusetts reveal that to date only 0.6 per cent of the x-rays of 9000 recruits have shown tuberculous lesions, including active, suspicious and apparently healed ones, the three groups being about equal in size. Calcified childhood lesions are not included in these figures.

Statistics from the Canadian and Australian armies Adamson⁷ writes from Canada that as a result of ordering a chest plate of every recruit there have been 1.06 per cent rejections because of tuberculosis. He adds, "The general conclusion, namely, that 20 recruits will be discarded for every one of the population that dies each year of tuberculosis, is likely accurate." These rejections are necessary because experience during and since the last war shows that "for every 100 killed in action, 6 have died of tuberculosis; for each 100 pensioned for wounds, 25 have been pensioned for tuberculosis."

Cooper⁸ reports that of 9000 recruits for the Australian army 1.33 per cent showed evidence in the lung fields of past or present tuberculous infection of the secondary adult type, whereas 0.55 per cent showed active pulmonary tuberculosis.

CASE FINDING IN THE APPARENTLY HEALTHY CIVIL POPULATION

The following studies on case finding in the civil population have been reported during the year. Plunkett and Mikoi⁹ report the results of routine x-ray examinations of 4853 adult admissions to fourteen general hospitals in ten cities of upstate New York during 1937 and 1938. In 128 of these, or 2.6 per cent, there was evidence of the reinfection type of tuberculosis. Of these, 51, or 1.1 per cent of the total, presented clinically significant lesions. In about half, tuberculosis had not been considered a possibility, and the survey revealed the first evidence of the disease. These and other published figures have been used as the basis for a campaign to make an x-ray examination of the chest of every patient admitted to general hospitals.

In a special supplement to the *American Review of Tuberculosis*, Edwards,¹⁰ the director of the Bureau of Tuberculosis for New York City, writes on

"Tuberculosis Case-Finding: Studies in mass surveys." Robins and Ehrlich¹¹ have summarized these studies in an article on "Group X-ray Surveys in Apparently Healthy Individuals." Their outstanding figures are the following:

High school students Of 14,177 high school students with an average age of 16.5 years, 0.4 per cent had active lesions.

Home relief population of Harlem In Harlem, 53,237 persons, predominantly Negro and Porto Rican, with an average age of 36.3 years, showed 3.1 per cent active and 1.0 per cent arrested tuberculosis.

Prison population In 2477 prisoners with an average age of 38.7 years, four fifths of whom were men, 5.9 per cent active and 5.3 per cent arrested disease was demonstrated.

Homeless men Among 3643 homeless, with an average age of 49.6 years, there was 5.2 per cent active and 10.9 per cent arrested disease.

Among the conclusions drawn were the following: In such studies the incidence of clinically significant pulmonary tuberculosis varies with the age, sex, race and economic level of the population studied. The greatest effort should be expended on adults and groups of low economic level. The majority of the cases, 70 per cent of the total, were discovered in the minimal stage. The incidence of active tuberculosis is lower in Negroes than in Whites among the apparently healthy population. This fact is surprising to most people, because the mortality rates for the Negroes by specified age and sex divisions are five to ten times those of the Whites, apparently owing to the fact that the Negro is more likely to develop acute exudative than fibrotic tuberculosis.¹²

Hedvall¹³ reports a new study on the incidence of tuberculosis in university students. X-ray studies of 638 medical students at the Lund University in Sweden showed 11.3 per cent pulmonary tuberculosis. He believes, but does not prove, that a large proportion of these infections are contracted during post mortem examinations. This possibility deserves further study.

Lyght¹⁴ reports on college students in this country. In 1938 and 1939 he found that there were 165 colleges supporting case finding by tuberculin tests and x-ray study. In these colleges 348,713 students were checked, and 241 or 0.7 per cent demonstrated clinically active disease. In 117 colleges where there was no case-finding program, 129,851 students were enrolled, and only 4 active cases were reported during the year.

REDUCING THE COST OF MASS X-RAY EXAMINATION

From the foregoing studies it is evident that one must look for early tuberculosis in the apparently healthy, but it is expensive to x-ray large

numbers. Therefore, much attention has been given to developing a cheap but effective method of x-ray examination. The following technics have been suggested and the results reported.

Fluoroscopy. The first method, and obviously the cheapest, is fluoroscopic examination. With the new fluoroscopic screen, a modern tube and an experienced observer, such an examination will bring to light almost all clinically significant cases, but a few potentially serious minimal cases will be missed. The best evaluation of this method is by Fellows and Ordway¹¹ of the Metropolitan Life Insurance Company, who state that in 1937, 2603 persons were examined by both fluoroscopy and standard x-ray films. The latter demonstrated pulmonary tuberculosis in 109 cases, in 14 of which the diagnosis had been missed on fluoroscopic examination, making the percentage of error 13. Of the 14 missed cases, "5 were latent or clinically insignificant, while 9 were considered clinically active." Another criticism of the fluoroscopic method is that it does not give a permanent record.

Miniature photographs of the fluoroscopic screen. Another suggested economy is to photograph on a small film the image on the fluoroscopic screen and thus eliminate the costly 14-by-17-inch standard film. Two sizes of film have been used for these fluorograms, the 35-mm. and the 4-by-5-inch. The camera holding the film has a special lens and is placed at the small end of a pyramid-shaped tunnel, with the fluoroscopic screen at the other end. The person to be x-rayed stands against the screen with the x-ray tube at the proper distance behind him. To ensure clear-cut shadows the fluorescent screen is seven times as fast as the usual Patterson screen. The cost of the complete equipment, including a \$700 rotating anode tube, is \$6000 to \$8000. If there is already a complete x-ray installation, the extra equipment required—the tunnel with fluoroscopic screen and camera with special lens—costs about \$2500.

Some investigators are enthusiastic about the 35-mm. film, but most agree that significant lesions are often missed in a small image that must be enlarged by a projector before it can be read. Present opinion favors the 4-by-5-inch film, which can be read without enlargement. Potter designed the apparatus and studied with Douglas and Birkelo^{12, 13} 1610 clinic cases, using both the standard 14-by-17 and the 4-by-5-inch film for each case. With the standard method they found 271 active tuberculous lesions, 7 of which were not visible in the small films. The missed lesions were very small and were obscured by a rib in the small film. The percentage of error is, therefore, 2.6. In a test run, 73 persons were x-rayed in sixty-five minutes

at a film cost of about one tenth that of the standard size. An additional argument in favor of the small films is the smaller space required for storage.

AIDS IN INTERPRETING THE X-RAY FILM

Whatever the x-ray method, there will always be a significant number of asymptomatic cases in which the most experienced roentgenologist will have difficulty in determining whether the shadow is that of an active or inactive tuberculous process. Furthermore, even if the lesion is active from the histologic standpoint, will it heal without ever giving symptoms? So much has been published about the value of the differential white-cell count and the red-cell sedimentation rate in determining activity that a review of the salient points is in order.

Differential white-cell count. The value of the differential count of the white blood cells depends on the theory that the increase in the number of each type of cell in the blood parallels the predominance of that type of cell in the tuberculous lesion itself. Therefore, an increase in the large mononuclear cells in the blood is said to demonstrate new tubercle formation in the lungs, with large numbers of endothelial monocytes forming the tubercles. On the other hand, if the tuberculous lesion is healing, the number of lymphocytes in the blood will be increased because there is a collar of lymphocytes encircling the tubercles. Lastly, if there is cavity formation in the lung tissue, the influx of polymorphonuclears will be accompanied by an increase in these cells in the blood. Various authors give the numbers and relative numbers of the different white cells in percentages, in counts per cubic millimeter, in the monocyte-lymphocyte ratio, or by the Medler index, which is a single number calculated from the number of polymorphonuclears, lymphocytes and monocytes. In general, the rules given hold, but the great weakness in the method is that small active lesions may appear in the x-ray film and may increase in size for at least a few weeks before any change is evidenced in the differential count. It is true, also, that the cell count may be normal in the presence of advanced fibrocavernous disease with positive sputum.

Red-cell sedimentation rate. Active infection of any kind is usually accompanied by an increase in the fibrinogen content of the blood and a consequent increase in the sedimentation rate of the red cells. If, therefore, there is an active tuberculous lesion, the sedimentation rate should be increased in proportion to the severity of the infection. Again, in general, the rule holds; unfortunately, however, minimal active disease may exist without changing the sedimentation rate. It has been found,

too, that once the rate is elevated, it may continue thus long after the process is clinically inactive. For this reason one cannot always wait for a normal sedimentation rate before discharging a patient from a sanatorium.

Relation between the differential count and sedimentation rate. From the few cases reported, it appears that the first change shown in the blood after the beginning of tubercle formation is an increase in the large mononuclear cells, and that the change in the sedimentation rate comes later. Then as the process heals, the differential count returns to normal before the sedimentation rate.

Young polymorphonuclears. Without going into detail, the statement may be made (again with reservations) that an active tuberculous lesion is accompanied by an increase in the young polymorphonuclear cells in the blood. The difficulty lies in the determination of just what cells are young polymorphonuclears, and this makes the test unreliable except in the hands of an expert.

Blood studies and prognosis. A single blood study must be interpreted cautiously, but frequently repeated studies may have value in determining prognosis. Steady improvement in the blood counts may point to a favorable outcome before there is clear-cut regression of the x-ray shadow. On the other hand, in selecting patients for thoracoplasty some surgeons refuse to operate if there is an increasingly unfavorable blood change.

Examination of the fasting gastric contents. The value of examining the fasting gastric contents for tubercle bacilli has already been mentioned in previous reviews and recently in an editorial in the *Journal*.¹⁴ Suffice it to say that the value of this examination is increasingly appreciated, and that the activity of a pulmonary process may often be proved by the finding of tubercle bacilli in the gastric contents of a patient without cough or expectoration.

Stiehm¹⁵ has studied the blood and gastric contents of 40 subclinical cases, and concludes:

Of available laboratory methods, the erythrocyte sedimentation rate was found to be normal in 90 per cent of the cases, and apparently gives little assurance that a lesion is either benign or inactive. The leukocyte reaction, where favorable, indicates a favorable prognosis. An unfavorable or equivocal leukocyte reaction, however, indicated an unfavorable course in only 50 per cent of the cases. Gastric aspiration with guinea pig inoculation is the most reliable method of proving both the diagnosis and activity of the lesion.

DEVELOPMENT IN X-RAY TECHNIC

So much is being said in the x-ray departments of large hospitals about "laminagraph," "planigraph" and "tomograph" that a word of explanation is in place.¹⁶ These terms all mean that the

new apparatus is designed to record the shadow of a specific plane or layer of the lung and eliminate the shadow of tissue in the other planes. The aim is to keep the focus on one plane while varying the focus on all other planes so as to blur their shadows. The film is exposed longer than in ordinary roentgenography, and both the tube and the film move in such a way that the purpose mentioned above is accomplished. The tube is located above the patient lying on the table, and moves in a plane parallel to that of the table. The film rests on a support under the table, and moves in the opposite direction from the tube. The two are joined in such a way that they move simultaneously. The plane desired in focus is at their fulcrum. Changing the level of the fulcrum makes it possible to x-ray successive levels of the chest.

The laminagraph is particularly helpful in demonstrating the large bronchi. Its main use in tuberculosis is to disclose cavities otherwise unseen because of overlying tissue. The real value of the procedure is yet to be established, and, of course, one of its drawbacks is the expense involved for the several films necessary to x-ray the different layers.

THE TREND OF SURGERY IN TUBERCULOSIS

The policy followed in these reports is not to discuss new methods until their practical value has been established, but at times one is justified in pointing out certain trends. The belief that incision into a tuberculous pulmonary process must lead to a permanent bronchial fistula or chest-wall sinus has so long been accepted that recent surgical experiences to the contrary are worthy of note. In certain cases it has been shown that lobectomy, pneumonectomy and cavity drainage may be performed as successfully in tuberculosis as in other diseases. Such procedures may be indicated, especially when bronchial obstruction makes physiologic drainage through the bronchus impossible. The time has not yet come, however, to discuss indications, contraindications and technics.¹⁷

MINOR NOTES

Chemotherapy. Articles on the use of sulfanilamide and allied compounds in tuberculosis continue to appear. The studies, in the main, have been experimental and the results somewhat confusing. Thus far there is little hope that these chemicals will be of value in clinical tuberculosis.¹⁸

BCC. Vaccination with the Calmette-Guérin bacillus is still being tried abroad and to a limited extent in this country. The wisdom of such vaccination remains questionable.

Twelve-day guinea-pig test. Pickoff¹⁹ injects silica powder subcutaneously into a guinea pig, and then into the same area injects the material suspected of containing tubercle bacilli. In twelve days, if there is a firm infiltration, the material is removed by syringe and stained for tubercle bacilli. Since it is known that tubercle bacilli develop more rapidly in the presence of silica, the method holds promise.

The supposed waxy capsule. Lembke et al.²⁰ give evidence from ultramicroscopic observations on tubercle bacilli that the oft-mentioned waxy capsule of the bacillus is a myth, and that actually the wax is distributed throughout the structure of the organism.

X-ray changes preceding a positive tuberculin reaction. Evidence is accumulating that in certain cases the x-ray shadow of a tuberculous process precedes the positive tuberculin reaction.²¹

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27131

PRESENTATION OF CASE

First Admission. A thirty-nine-year-old man entered the hospital complaining of low-back pain.

Three years before admission the patient had had lobar pneumonia complicated by an empyema, which was drained by rib resection. A satisfactory convalescence followed, but ever since he had tired rather easily. During the year before admission he suffered from frequent infections, notably acute axillary abscesses for which incision and drainage were found necessary. He entered the hospital complaining of low back pain radiating down the right leg. It was of gradual onset and had been present for five days, but the patient stated that he had had many such attacks during the past nineteen years, the usual diagnosis being sacroiliac strain.

The patient had had an appendectomy twenty-two years before admission, and four years later an attack of jaundice with clay-colored stools; three years before entry, he had had a streptococcal sore throat.

On examination the patient was well developed and well nourished, somewhat pale and appeared chronically ill. Examination of the chest revealed a systolic scratch, which became accentuated during expiration and disappeared on inspiration in the third interspace immediately to the left of the sternum; the blood pressure was 140 systolic, 90 diastolic. Examination of the abdomen was negative. There was tenderness in the right sacroiliac joint, and all movements were limited here and in the right leg, because of pain. Examination of the nervous system was negative.

The temperature, pulse and respirations were normal.

Examination of the urine showed a ++ test for albumin. Examination of the blood showed a red-cell count of 2,690,000 with a hemoglobin of 53 per cent, and a white-cell count of 6300. The differential count was normal. The color index was 1.06, the volume index 1.08, the cell volume 25 per cent, the sedimentation rate 71 mm. in one hour. The nonprotein nitrogen of the blood serum was 24 mg., the protein 10.7 gm., the calcium 11.7 mg., the phosphorus 3.6 mg. per

100 cc., the phosphatase 6.8 Bodansky units, the total cholesterol 64 mg. per 100 cc.; the chlorides were 95.1 milliequiv. per liter. A blood Hinton test was negative. A bromsulfalein test showed less than 5 per cent retention of the dye in the serum; a formal-gel test was strongly positive; a phenolsulfonephthalein test was normal. A lumbar puncture gave an initial pressure of 250 and a final pressure of 200 mm. of spinal fluid after the removal of 10 cc. The cells were not increased, and the protein was 57 mg. per 100 cc.; the spinal-fluid Wassermann test was negative.

X-ray films of the spine showed some increased density about the articulation between the fifth lumbar vertebra and sacrum on the right side. The articulating surfaces were indistinct, and the density of the bone increased. There was no displacement and no narrowing of the intervertebral spaces. The other joints appeared normal. There were no changes in the structure of the bones.

Two weeks after admission a sternal puncture was performed, and it was found that 25 per cent of the nucleated cells in the marrow consisted of plasmocytes and plasmoblasts. Following this procedure, many unsuccessful attempts were made to demonstrate Bence-Jones protein in the urine. X-ray studies of the skull, cervical spine and long bones showed no variation from normal. During hospitalization an abscess developed in the left axilla and was incised and drained. The patient was given three blood transfusions, and discharged six weeks after admission, at which time the blood showed a red-cell count of 2,660,000 with a hemoglobin of 60 per cent and a white-cell count of 5000.

Second Admission (eleven days later). In the interval, x-ray therapy had been instituted and the patient felt a bit stronger, but still noticed palpitation and shortness of breath on exertion. Ten days after discharge he suffered a fainting spell, and hospitalization was therefore advised. The cervical, axillary and inguinal lymph nodes were palpable, and the spleen could just be felt on deep inspiration. The blood showed a red-cell count of 2,700,000 with a hemoglobin of 53 gm., and a white-cell count of 3700. Bence-Jones proteinuria could not be demonstrated. X-ray treatment was discontinued, and the patient was given one 500-cc. blood transfusion and discharged a week later.

Third Admission (three weeks later). Since leaving the hospital the patient had been confined to his bed most of the time, and shortly after returning home developed a severe nosebleed, which lasted for two days. Two weeks before admission he caught cold, and after a bout of sneezing a "red blurring" affected sight in his right eye, at first in the upper field, then gradually spreading over

the whole field of vision. In general he felt weak, and suffered from a right-sided headache and almost complete deafness in the right ear. On examination he had obviously lost ground and was pale and emaciated. Examination of the fundi showed many hemorrhages throughout all layers of both retinas with numerous patches of exudate. A well-circumscribed hemorrhage was present in the right macula. The cervical, axillary and inguinal lymph nodes were palpable, and those in the left axilla were still draining. A systolic murmur was audible over the entire precordium, maximal at the apex; the blood pressure was 114 systolic, 70 diastolic. The spleen and liver were just palpable. There was slight clubbing of the fingers. The blood showed a red-cell count of 1,340,000 with a hemoglobin of 2.5 gm., and a white-cell count of 4100. The differential count and the platelets were normal.

The patient remained in the hospital for approximately two months and during this time received fourteen 500-cc. blood transfusions. Six weeks after admission the clotting time and clot retraction were normal, the prothrombin time 16 seconds (normal 19 seconds) and a hematocrit reading 16.3. One epistaxis occurred, and blood films on two occasions showed 1 per cent atypical lymphocytes and 1 per cent blast cells. At the time of discharge the patient was symptomatically improved, but the blood showed a red-cell count of 1,410,000 with a hemoglobin of 45 per cent and a white-cell count of 1500.

Fourth Admission (six months later). On three occasions during the two months after discharge the patient was given a 500-cc. blood transfusion. He improved remarkably, lived a normal life and was free from symptoms until three weeks before admission, when he noticed dyspnea on exertion associated with a feeling of fullness in the upper abdomen.

On examination the patient appeared tired and was pale. The neck veins were dilated, and showed pulsations of both auricular and ventricular character. There was considerable enlargement of the heart, the sounds were of fair quality, but there was a slight gallop rhythm; the blood pressure was 120 systolic, 80 diastolic. The liver and spleen were not palpable, but the abdomen was tender in the liver region. There was no peripheral edema.

The urine showed a + test for albumin, but no Bence-Jones protein. The blood showed a red-cell count of 3,210,000 with a hemoglobin of 10.2 gm., and a white-cell count of 6700. The non-protein nitrogen of the blood serum was 17 mg., the protein 7 gm. per 100 cc.

An x-ray film of the chest showed that the diaphragm was rather high on both sides but

moved fairly well with respiration. The lung fields were of normal brilliancy throughout. The vascular shadows at both lung roots were increased in size and density. The heart shadow was enlarged in all diameters, and the apex was blunted; the greatest increase was to the left in the region of the ventricle. There were no visible mediastinal masses; the great vessels appeared normal.

Films of the abdomen showed the liver shadow fairly well; it did not appear to be greatly enlarged; the spleen was indistinct, but did appear to be somewhat larger than normal. The kidney outlines were visible and normal, or slightly increased in size. There was no evidence of a lesion in the bones. A Graham test was normal. An electrocardiographic recording showed a normal rhythm at 90. T₁ was upright, T₂ low and slightly diphasic with probably slight late inversion. T₃ showed late inversion, and Q₃ was rather prominent. The P waves and PR interval were normal. This was repeated at the end of deep inspiration and showed a normal rhythm at 85; T₁ was very low, T₂, T₃ and T₄ moderately inverted; R₄ was present.

The patient was discharged on the second hospital day.

Fifth Admission (two weeks later). The patient was given digitalis at home, but did not improve. Dyspnea was still present, and he suffered from an unpleasant sensation of pressure in the abdomen and chest. Anorexia and malaise developed, and he began to lose weight. Additional findings on physical examination were as follows: The cardiovascular abnormalities were as before, but the pulmonary second sound was now greater than the aortic. A few rales were heard at both lung bases, and the tender liver was 5 cm. below the costal margin. The blood picture was much the same, and the platelets were decreased.

An electrocardiogram showed normal rhythm at 95. The P waves and PR interval were normal. There was some slurring of the QRS complexes, and their duration was about 0.1 second. S₁ and Q₃ were prominent; T₁ was low, but upright, T₂ and T₃ inverted. There was a bizarre Lead 4, with ST₄ slightly elevated and T₄ diphasic and slightly inverted. During hospitalization the patient was given x-ray therapy totaling 1000 r in the three weeks.

Final Admission (two weeks later). In the interval the patient had gradually lost ground. At the time of entry he was weak and cyanotic and the neck veins very distended. The heart findings were unchanged except for an appreciable increase in the systolic apical murmur. There was dullness at the right base, and rales at the left

base. The liver was larger; there was no peripheral edema. The patient was given two more 500-cc. blood transfusions, but lapsed into coma and died on the ninth hospital day, approximately one year after his first admission.

DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG: There are many confusing leads in this case. I wonder if Dr. Holmes would show us the x-ray films, especially those of the spine and lungs.

DR. GEORGE W. HOLMES: I am quite familiar with this case, and I shall try not to give too much of it away. These films were taken because of pain in the back to see if there was a bone lesion. All that is described in the record is of no significance except for the statement that the spine showed increased density, and whether it actually does might even be questioned. The bones do seem more dense than one would expect in a sick person. Except for that, the x-ray evidence is of only negative value.

DR. LUDWIG: Is there any evidence of disease in the ribs?

DR. HOLMES: No.

DR. LUDWIG: I should like to ask if the marrow cavities seem increased in size.

DR. HOLMES: I think so, but that is a very unreliable finding, merely a guess. The skull is essentially normal.

DR. LUDWIG: Do these fine markings in the skull mean anything?

DR. HOLMES: I do not think so.

On the film taken at the fourth entry, there is definite evidence of variation in the heart and lungs. The heart shadow is increased in size. The apex is distinctly blunt, and the curve of the left ventricle is prominent. The enlargement is more to the left than in any other direction. There are also changes in the hilar region, and I think that the interpretation given was correct, that is, these changes were probably vascular and not neoplastic in origin.

DR. LUDWIG: Was there any definite evidence of tumor in the hilar nodes?

DR. HOLMES: There was no definite evidence of enlarged lymph nodes. I do not believe that one can absolutely rule out tumor. On the other hand, the appearance could be interpreted, along with the change in the heart shadow, as increased hilar shadows due to heart failure.

DR. LUDWIG: From the x-ray point of view, what should you say caused this condition?

DR. HOLMES: If I could dissociate what I know, I should say that it was the heart of hypertension.

DR. LUDWIG: Which, of course, the patient did not have.

DR. HOLMES: I think it is safe to say that the liver is enlarged. Here we see the spleen, certainly not very large, but on the borderline of being enlarged. The kidneys also look a little large. The patient was a rather small man, and the kidneys were not a long distance away from the film to account for magnification.

DR. LUDWIG: I think the kidneys should be large.

DR. HOLMES: So far as one can tell from the x-ray evidence, they are.

DR. LUDWIG: I have the impression that much of the evidence in this case is not very helpful in establishing the diagnosis that I think should be made. As I read this over I believed that the key to the correct diagnosis lay in the paragraph giving the laboratory findings. A number of things in that paragraph taken separately might not help, but taken together do. In the first place, albuminuria persisted throughout the illness; the patient had a normochromic, perhaps even somewhat hyperchromic, anemia; he had an extremely rapid sedimentation rate, a very definite hyperproteinemia of 10.7 gm., a slightly elevated serum calcium, a normal serum phosphorus and normal phosphatase, and a positive formol-gel test. The nonprotein nitrogen, chlorides, and liver-function and renal-function tests were within normal limits. I cannot explain the low cholesterol.

To go back to the story of back pain radiating down the leg, I first thought that it might be associated with the disease from which I believe the patient was suffering, and it may well be; but I do not believe if the attacks had been present for nineteen years that the two are related. A ruptured intervertebral disk might very well have caused these attacks. I have seen patients with ruptured disks in whom attacks persisted over such a period of time. The elevated total protein in the spinal fluid is confirmation, but there is no other evidence to allow that diagnosis.

In the second paragraph we are told that the sternal puncture showed that 25 per cent of the nucleated cells consisted of plasmocytes and plasmoblasts. This finding together with the clinical findings spell multiple myeloma in spite of the fact that there is nothing else to go with it. Albuminuria is extremely common in multiple myeloma—75 per cent of the cases reported in the literature have it. The absence of Bence-Jones protein is disturbing, but it is present in only half the reported cases. The normochromic or hyperchromic anemia is found in 90 per cent. The slight hypercalcemia and normal phosphorus and phosphatase are also consistent. Most striking is the high serum protein, —10.7 gm.,—which is one of the most typical findings in multiple myeloma. It is

probably secondary to the elevation of the globulin fraction, which also accounts for the very rapid sedimentation rate and the positive formol-gel test. In addition, a high globulin content in the serum tends to cause clotting with Hayem's solution if that is used as a diluent in doing the red-cell count. Whether or not that was noted here I do not know. Dr. Holmes has already discouraged me from the x-ray point of view. I should have expected evidence of multiple myeloma in the bones, and we have none unless we can interpret increased marrow spaces in the long bones as secondary to tumor in this location.

This patient ran a course of anemia and increasing cardiac difficulty. We are told that a little later the spleen was palpable and that the lymph nodes became enlarged. In about half the cases of multiple myeloma recently autopsied here that Dr. Jacobson got together in 1929 the spleen was enlarged, and it is known that in multiple myeloma metastases to internal organs and also to lymph nodes may occur, although this is exceedingly rare. I do not know of any other condition that would give the sternal biopsy findings that we have in this case. If we grant that the patient had multiple myeloma, I think we still have a great deal to explain. What happened to him just before the third admission? The "red blurring," the deafness in the right ear, and right-sided headache, I should be inclined to account for on the basis of hemorrhage into the retina and also perhaps cerebral hemorrhage. We know that he had anemia and probably decreased platelets as well, which may have produced a tendency to bleed. The exudate in the retina is a little disturbing in that respect. The serum protein was normal on this admission. Perhaps Dr. Jacobson can tell us whether in any of his cases the protein returned to normal. I do not know whether that occurs in multiple myeloma.

Then we plunge into what is for me an uncharted field,—electrocardiography,—and I shall have to ask for help. I should interpret the findings as indicating a marked degree of myocardial damage. Can anyone help me?

DR. HOWARD B. SPRAGUE: It is difficult for me, as it is for Dr. Holmes, to dissociate myself from the knowledge of the case, because I came in through the back door of electrocardiography. I can only say that in the original interpretation of the electrocardiogram before I saw it, it was suggested that there was some myocardial coronary disease. We took special respiratory tracings to see whether we could change the direction of the T waves by change in the position of the heart, but the findings remained, and I suggested that they

might mean pericardial disease—but I shall discuss that later.

DR. LUDWIG: Certainly, so far as I am concerned, this cardiovascular picture is very mysterious. Here is a man with a heart condition that looked as if it were due to hypertension, and he had no hypertension. It may be—if my original diagnosis of multiple myeloma is correct—that the renal changes associated with this disease play a part. However, I should expect, if that were so, that there would have been some hypertension. In some of the cases of myeloma with secondary nephritis, the patients have had hypertension, but in others it is absent. If this man had some other form of neoplastic disease, I should seriously suspect cardiac metastases. He died primarily a cardiac death, became increasingly weak, cyanotic and dyspneic, had dullness at the right base, rales at the left base, and evidence of enlargement of the liver and spleen, probably due to congestion. The kidneys probably were increased in size and may present the picture seen in these organs in multiple myeloma, a nephritis due supposedly to a plugging of the tubules with Bence-Jones protein. In summary, I think that one must make a diagnosis of multiple myeloma. I am unable to explain the cardiovascular signs and symptoms. It may be that the extensive radiation therapy accounted for the atypical course of the disease and the absence of bone changes.

DR. FRANK T. HUNTER: Is it possible to find out whether that second serum protein of 7 gm. was done by the Kjeldahl or the specific-gravity method? We recently found in multiple myeloma that the specific-gravity procedure has no value. One can get a perfectly normal protein with that method and with the Kjeldahl method double it. I had one patient with a Kjeldahl value of 10 gm. and a specific-gravity value of 6.5.

DR. WILLIAM B. BREED: I will say that by the same process of thought and on the same basis of laboratory evidence we used myeloma as a working diagnosis through until the end. I think it is wrong to ignore the finding of these cells in the sternal smear. The smear was verified by Dr. Jacobson and Dr. Mallory. I think that some thing should be said about the x-ray treatment in this case. Dr. Holmes was interested in it and although there had not been much success in the treatment of such cases with deep therapy Dr. Holmes thought that it might be possible to change the situation from a rather acute one into a chronic one by x-ray therapy. The patient was given between December 21, 1939, and July 11, 1940, 1550 r by the quadrant technic, which include the chest and the abdomen, once or twice weekly.

Then during the summer, following this treatment and fourteen transfusions, he had a remission. He had a happy summer and was well. The reason we stopped the x-ray treatment was that his blood was so low he had to have a transfusion once a week. We did not know exactly whether he got better because we stopped the x-ray or because he got delayed benefit from the x-ray therapy. Dr. Sprague saw him because of the electrocardiographic abnormality. He noted it in the laboratory and called me up to ascertain if this patient had pericarditis. I said that so far as I knew he had no pericarditis, but I asked Dr. Sprague to see him. We decided that he did not have it and went through the same process of thinking that Dr. Ludwig did in the question of whether he had some involvement of the heart or pericardium with tumor tissue. He was given x-ray treatment to the mediastinum—1000 r between December 3 and 17—on the basis that we might relieve some pressure that was interfering with the venous return; but to no avail. I refused to transfuse him further, and he died of a combination of anemia and cardiac failure.

Perhaps Dr. Holmes would like to say something more about the treatment.

DR HOLMES: As Dr. Breed said, our diagnosis was multiple myeloma. That in itself is not a very favorable type of disease to treat by radiation. It is usually a generalized disease, and the area that one has to treat is so large that it is almost impossible to accomplish anything. Furthermore, it is not a particularly sensitive tumor, but if this patient had myeloma, it was certainly an atypical form. There was no involvement of the bone, which is one of the characteristic findings in the usual case of myeloma. We assumed that if it was myeloma, it was a very rapidly developing, very active type and for that reason might be more sensitive to radiation than the ordinary case. We had had some experience with leukemia, using this method of dividing the body into four areas and giving one quadrant, once a week, a rather small dose, taking eight weeks to go over the whole body. We consequently thought we were justified in trying it on that basis. As Dr. Breed said, we did not know whether we were successful in changing it into a more chronic form. The patient certainly had a good summer for some reason or other. We considered the danger of destroying what little blood-forming organs he had too great to continue, and we stopped.

DR SPRAGUE: He entered with evidence of rapid enlargement of the heart, which could be checked against previous x-ray films. The electrocardiogram also could be checked against previous elec-

trocardiograms that Dr. Breed had, and showed definite change. The patient had a big, dilated heart with gallop rhythm and evidence of both right-sided and left-sided failure of relatively mild degree at first. Later he presented more evidence of right-sided failure. However, in a general myocardial process the right ventricle generally fails first because it is the weaker chamber. The electrocardiogram was consistent with pericardial involvement, not necessarily pericardial fluid, and there was no definite evidence of constrictive pericarditis. There was the factor of anemia to account for the dilatation, and I thought the best bet probably was an infiltration of the pericardium, and perhaps the myocardium, by the underlying process, plus the anemia.

DR BERNARD M. JACOBSON: The serum protein of 10.7 gm, and several subsequent determinations were done in my laboratory by the gravimetric method, and were always high.

I have never seen a bone marrow with so many immature plasma cell elements as this, suggesting something very acute or malignant. It is true that multiple myeloma is accompanied in many cases by spontaneous symptomatic remissions just as dramatic as the spontaneous remissions in pernicious anemia. It is impossible to explain them. Yet a patient may feel better despite the fact that the bone destruction seen by x-ray may be advancing all the time. One of the most difficult things for all of us to believe is that as many as 30 per cent of cases of myeloma, judging from a series of approximately 35 cases that we have studied, will have bones completely negative by x-ray study even at the time of death. One should certainly not hesitate to make a diagnosis of myeloma because the bones are normal.

CLINICAL DIAGNOSIS

Plasma-cell myeloma

DR. LUDWIG'S DIAGNOSES

Multiple myeloma

Cardiac failure.

Ruptured intervertebral disk?

ANATOMICAL DIAGNOSES

Plasma cell myeloma, diffuse
Probable reticulum cell sarcoma of the femoral marrow.

Pulmonary endarteritis

Cor pulmonale.

Adhesive pericarditis

Pulmonary edema.

Chronic passive congestion of liver, spleen and kidneys.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: I am sorry time is short, because I am sure we should all like to continue this discussion. The autopsy showed a considerably enlarged heart, weighing over 500 gm., and an adhesive pericarditis. The adhesions seemed relatively recent. They could be stripped away by blunt dissection for the most part, and there was none of the marked thickening that one sees in the pericarditis of Pick's disease. I personally found it hard to believe that the pericardium could have been responsible for the cardiac failure. We see this degree of adhesive pericarditis too frequently in patients without cardiac symptoms. The thing that impressed me at the time of autopsy was the dilatation of the right ventricle and especially the dilatation of the pulmonary conus. Despite its dilatation, the right ventricle measured 5 mm. in thickness. I therefore felt justified in making a gross diagnosis of cor pulmonale. The lungs were very large and extremely wet and edematous. Grossly we could not find any atheroma in the pulmonary arteries; microscopically, however, all the minute pulmonary arteries showed an obliterative endarteritis. I have little doubt that the immediate cardiac difficulty was a cor pulmonale, secondary to pulmonary endarteritis. When the endarteritis developed, I have no idea. It is conceivable that radiation might have been the cause, but the amount of x-ray treatment was hardly great enough to make that probable.

The liver was very much enlarged, weighing 2500 gm., and showed the most extreme grade of congestion, with hemorrhagic necrosis of at least three quarters of every lobule, only a few viable liver cells persisting at the periphery. The spleen was enlarged also by passive congestion. The kidneys together weighed 600 gm., mostly due to edema. There were no casts in the tubules and nothing to justify a diagnosis of so-called "myeloma kidneys." I should like to inject a word of caution regarding interpretation of puzzling findings in cases of myeloma by the assumption of extraosseous myelomatous infiltrations. They are of extreme rarity. We have never seen any of significant degree in this laboratory. Compensatory hematopoiesis would be a more likely cause of enlargement of liver or spleen.

The proof of a diagnosis of myeloma must come, of course, from examination of the bone marrow. The picture in this case was rather puzzling and raises many questions, which I cannot answer.

An abnormal number of plasma cells were present in most of the sections studied, but in none was the proportion greater than 10 to 15 per cent of the nucleated cells, whereas in the original bone-

marrow aspirations they made up 25 per cent. In the intervening period they had apparently decreased rather than increased. This may have been the result of the radiotherapy, and might be interpreted as evidence of success. On the other hand the patient's anemia after a temporary remission had grown more severe. I have always assumed that the mechanism of anemia in cases of myeloma was that of progressive replacement of the hematopoietic marrow by tumor cells, a myelophthisic anemia. Certainly that was not the case here. The normal marrow elements were not decreased in number although they did show some shift to the left in differentiation. Even the marrow fat was not greatly decreased in amount. I believe we must conclude that this patient had myeloma, but I do not believe that we can attribute his death directly to it.

A further puzzle was added by a section of the femoral marrow. This had been noted to be deep red on gross examination. Microscopically it appears neoplastic, but the cells are certainly not plasma cells or their derivatives. They appear for the most part to belong to the clasmotocytic group, though a very large proportion of them are multinucleated. I am in doubt how this should be classified but believe it falls closest to the reticulum-sarcoma group. We found no evidence of similar neoplasm in any of the other bones examined, but six bones do not constitute a very large proportion of the human skeleton, so that we really do not know how extensive it may have been.

CASE 27132

PRESENTATION OF CASE

A sixty-one-year-old business man complained of substernal pain.

The patient was perfectly well until three days before consulting his physician, when he was seized with a severe substernal pain, which radiated down both arms to the wrists, where it produced considerable pain. The attack lasted from thirty to sixty seconds, then subsided and the patient felt quite well again. Exactly similar pains occurred from five to ten times a day during the next three days before he sought advice. It was unrelated to effort and occurred with greatest intensity at about three o'clock in the morning, when it awakened the patient. He felt perfectly well between times, and there was no dyspnea, orthopnea or cough. The patient was a tense, highly strung and active business man.

The past and family histories were irrelevant. Physical examination was entirely negative, including the heart, which was not enlarged to per-

cussion. The sounds were regular and of fair quality, the rate 74, and there were no murmurs. The blood pressure was 130 systolic, 80 diastolic.

The patient remained in bed for the next three days, but the attacks did not decrease in number and remained unrelated to effort; the effectiveness of nitroglycerin could not be determined because of the short duration of the pain, but it did appear to abort a few of the longer attacks. He reported to his physician at the end of this time, and physical examination was again entirely negative. Examination of the urine and blood was negative, and a blood Hinton reaction was negative. An electrocardiographic recording was normal.

The patient continued to have these attacks. At midnight two weeks later he awoke with a severe agonizing substernal pain radiating to both wrists. His physician was summoned some five hours later, and it appeared that the patient had been sitting in a chair writhing in agony during this time. His skin was white, and he was obviously in extreme pain. Even then the only change in physical examination was a much poorer quality of heart sound; the blood pressure was 120 systolic, 80 diastolic, the pulse 70. One-half grain of morphine gave great relief, and the patient dropped off to sleep. Three hours later he became cyanotic and developed a cough, rales being heard throughout both lungs. Digitalization was started but the patient suddenly died fourteen hours after the onset of pain.

DIFFERENTIAL DIAGNOSIS

DR SYLVESTER MCGINN. This case is rather unique for these exercises in that there is not a single abnormal physical or laboratory finding to help in making the diagnosis. At least it emphasizes the importance of history in any cardiac examination. I presume the diagnosis could have been made about as well over a telephone as it could at the bedside. The syndrome of angina pectoris with some typical and atypical features runs through the entire history. We have a man who had apparently always been in good health and suddenly was overcome with an illness, which from the very beginning had the earmarks of being very serious and within three weeks caused sudden death, a death that from the nature of the symptoms might well have been anticipated.

Among the causes of sudden death in a man of his age, although there is nothing particularly in the record to indicate it, would be dissecting aneurysm. The pain in this case was not one to suggest it. The patient had neither back pain, abdominal pain nor pain in the legs. Furthermore, it is un-

usual to find dissecting aneurysm in a patient without hypertension. Pulmonary embolism could cause sudden death, but here we have a man suffering five to ten attacks a day for a period of weeks, and that does not sound like pulmonary embolism, nor did he have a pleuritic type of pain. Angina decubitus with a gradual and impending coronary occlusion seems to me to be the most likely diagnosis. The term "angina decubitus" means a very severe angina with attacks occurring even when the patient is at rest. Such cases are quite uncommon. We see them in syphilitic heart disease, but this man had a negative Hinton reaction. I have seen several cases with severe anemia associated with coronary sclerosis, but this man's blood study was negative. Some patients with aortic stenosis may have angina decubitus, but physical examination of the heart in this case was normal, so that I think we must rule out a valvular disturbance. In trying to reconstruct the case, it seems to me there was a small, partial coronary occlusion and finally the occlusion became complete either by dislodgment of an atheromatous plaque or a gradually increasing thrombosis. I assume that complete occlusion occurred at the final episode, when he died. Had it occurred prior to that time we should probably have found definite evidence of myocardial infarction, either in the physical findings or in the electrocardiogram that was reported. These negative findings would rule out myocardial rupture as the final cause of his demise. I should like to make a diagnosis of coronary sclerosis with coronary occlusion, and angina pectoris with an impending complete occlusion.

DR HOWARD B. SPRAGUE. Should you like to suggest that he had a process in the right coronary artery, because he had pain in the right arm?

DR MCGINN. Not with a normal electrocardiogram.

DR ALFRED KRANES. There are several points of interest in the story. The first is the suddenness and severity with which it started. The patient insisted that he had been quite well previously. Several months before he was seen, he had applied for a large insurance policy and had passed the physical examination successfully. That fact might, I suppose, make one slightly suspicious that the history might not be entirely accurate. At any rate, the insurance company feels that way about it. The second point is that the pain was not related to effort. He could run up a flight of stairs without any difficulty but had a good deal of pain lying quietly in bed at night. Finally the electrocardiogram taken ten days before his death was entirely normal. I am sorry I did not bring it with me.

DR SPRAGUE. A person, of course, can have a

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: I am sorry time is short, because I am sure we should all like to continue this discussion. The autopsy showed a considerably enlarged heart, weighing over 500 gm., and an adhesive pericarditis. The adhesions seemed relatively recent. They could be stripped away by blunt dissection for the most part, and there was none of the marked thickening that one sees in the pericarditis of Pick's disease. I personally found it hard to believe that the pericardium could have been responsible for the cardiac failure. We see this degree of adhesive pericarditis too frequently in patients without cardiac symptoms. The thing that impressed me at the time of autopsy was the dilatation of the right ventricle and especially the dilatation of the pulmonary conus. Despite its dilatation, the right ventricle measured 5 mm. in thickness. I therefore felt justified in making a gross diagnosis of *cor pulmonale*. The lungs were very large and extremely wet and edematous. Grossly we could not find any atheroma in the pulmonary arteries; microscopically, however, all the minute pulmonary arteries showed an obliterative endarteritis. I have little doubt that the immediate cardiac difficulty was a *cor pulmonale*, secondary to pulmonary endarteritis. When the endarteritis developed, I have no idea. It is conceivable that radiation might have been the cause, but the amount of x-ray treatment was hardly great enough to make that probable.

The liver was very much enlarged, weighing 2500 gm., and showed the most extreme grade of congestion, with hemorrhagic necrosis of at least three quarters of every lobule, only a few viable liver cells persisting at the periphery. The spleen was enlarged also by passive congestion. The kidneys together weighed 600 gm., mostly due to edema. There were no casts in the tubules and nothing to justify a diagnosis of so-called "myeloma kidneys." I should like to inject a word of caution regarding interpretation of puzzling findings in cases of myeloma by the assumption of extraosseous myelomatous infiltrations. They are of extreme rarity. We have never seen any of significant degree in this laboratory. Compensatory hematopoiesis would be a more likely cause of enlargement of liver or spleen.

The proof of a diagnosis of myeloma must come, of course, from examination of the bone marrow. The picture in this case was rather puzzling and raises many questions, which I cannot answer.

An abnormal number of plasma cells were present in most of the sections studied, but in none was the proportion greater than 10 to 15 per cent of the nucleated cells, whereas in the original bone-

marrow aspirations they made up 25 per cent. In the intervening period they had apparently decreased rather than increased. This may have been the result of the radiotherapy, and might be interpreted as evidence of success. On the other hand the patient's anemia after a temporary remission had grown more severe. I have always assumed that the mechanism of anemia in cases of myeloma was that of progressive replacement of the hematopoietic marrow by tumor cells, a myelophthisic anemia. A further puzzle was added by a section of the femoral marrow. This had been noted to be deep red on gross examination. Microscopically it appears neoplastic, but the cells are certainly not plasma cells or their derivatives. They appear for the most part to belong to the clasmotocytic group, though a very large proportion of them are multinucleated. I am in doubt how this should be classified but believe it falls closest to the reticulum-sarcoma group. We found no evidence of similar neoplasm in any of the other bones examined, but six bones do not constitute a very large proportion of the human skeleton, so that we really do not know how extensive it may have been.

CASE 27132

PRESENTATION OF CASE

A sixty-one-year-old business man complained of substernal pain.

The patient was perfectly well until three days before consulting his physician, when he was seized with a severe substernal pain, which radiated down both arms to the wrists, where it produced considerable pain. The attack lasted from thirty to sixty seconds, then subsided and the patient felt quite well again. Exactly similar pains occurred from five to ten times a day during the next three days before he sought advice. It was unrelated to effort and occurred with greatest intensity at about three o'clock in the morning, when it awakened the patient. He felt perfectly well between times, and there was no dyspnea, orthopnea or cough. The patient was a tense, highly strung and active business man.

The past and family histories were irrelevant. Physical examination was entirely negative, including the heart, which was not enlarged to per-

NATIONAL CANCER MONTH

This year, with attention distracted by world turmoil, it is all the more necessary to have some specific event to focus interest, at least in passing, on cancer and its relation to human beings, since this problem—war or no war, emergency or no emergency—is always with us. Hence, it is appropriate that April has been set aside as National Cancer Month.

During the coming year it is to be hoped that the progress made in this field in previous years will continue. However, it is all too easy to forget that the problem is far from solved and that, in the need for airplanes, tanks and submarines, the less spectacular necessity for continued effort against cancer persists. The very fact that Massachusetts has in recent years been showing a fall-

ing death rate from this disease is all the more reason to intensify efforts to overcome it.

Year by year, advance in knowledge of the treatment not only of cancer itself but also of pre-cancerous conditions has increased, and there is now more than a glimmering of hope that a fair proportion of cutaneous cancers, and even some cancers of the uterine cervix, may be prevented by adequate care of certain types of premalignant lesions.

Additional experience in the field of high-voltage and super-voltage radiation therapy, the use of the new radio-active isotopes and the advances made in the field of thoracic surgery have provided further means by which various forms of cancer may be more successfully treated.

Education to permit the application of this therapy early in the development of a neoplastic process is an essential part of any effort to meet the problem. The willingness of the medical profession to aid in this educational work has been and must continue to be an important factor in reducing mortality from cancer.

THE TREATMENT OF THE PSYCHONEUROTIC

THE principal forms of treatment now in vogue for the psychoneurotic patient, evolved through centuries of experience, are the "psychobiological" approach, advocated and developed in America by Adolf Meyer, the "persuasive" method of Dubois and the "re-educational" form, exemplified by the work of the late Austen Fox Riggs and often spoken of as the "Stockbridge method." All these procedures have their adherents in the treatment of the largest group of patients seen in medical practice. Success is claimed for each one or for various combinations. Few analytic evaluations of the results have, however, been reported, and the importance or unimportance of any one method is vaguely delimited in the minds of most physicians. How would a group of patients treated by the Meyer method compare with a similar number under the guidance of the re-educational form of Riggs, or the persuasive method of Dubois? No one knows, since no such analyses have been made.

For one type of treatment, however, that of Riggs, data are now available.* Such reviews are needed of all "systems," for it is largely by analysis of the results that a rational conclusion can be drawn regarding the effectiveness of treatment.

The Stockbridge method is based on certain concepts of the psychoneuroses as understood by Riggs. A constitutional vulnerability was considered the basic etiologic factor, made up of two main components, "a marked imbalance of the instinctive drives and a high degree of hypersensitivity, deep-rooted characteristics which profoundly influence the quality and intensity of the individual's habitual responses and predispose him to psychoneurotic illness." The hypersensitive person, especially if subjected to early unfavorable environmental influences, tends to develop distorted values, impractical ideals and faulty attitudes and habits. Immaturity of thought and action is the commonest factor; inner struggles, discordant relations, anxiety, insecurity, distressing feelings and many other symptoms may result.

With such a basis for a psychoneurosis, the Stockbridge treatment consists, in brief, of an attempt to aid the patient in obtaining insight into the development of his disorder by means of a painstaking personality review—usually by straightforward discussion. After a fair measure of insight is obtained, rehabilitation is attempted by weighing the useful against the unsatisfactory patterns of response. Finally the patient is tested against a normal background by living with his fellow men in an unrestricted environment.

To evaluate the results of treatment, a statistical study has been made of more than a thousand patients treated at Stockbridge during a twenty-five-year period from 1910 through 1934. The data coded were based on case histories, and it should be noted that only 4 per cent of the histories were thought to be excellent, 10 per cent good, 50 per cent fair and 37 per cent meager. To this was added information received after discharge of the patient in 96 per cent of the cases. In the estimates of the level of adjustment reached

by all the patients, 34 per cent were described as good, 48 per cent fair, 14 per cent poor and 4 per cent unknown. Thus a third made a good recovery, and over four fifths a good or fair recovery. Considering the fact that the median length of the first visit to Stockbridge for women was only thirty-four days and for men only twenty-six days, although the total duration of treatment in the majority of cases, owing to return follow-up visits, was much longer, the results of therapy may be said to be good. The chief weakness of the survey, however, lies in the relatively poor case records, a fault that should be overcome in the future.

One cannot estimate the value of the Stockbridge method as compared with other methods of treatment, since no satisfactory standards have been set up by other clinics. A beginning has been made in the Stockbridge survey. It is expected that others will follow the excellent example set by Coon and Raymond.

MEDICAL EPONYM

HAYGARTH'S NODOSITIES

Haygarth's nodosities were described by John Haygarth (1740-1827), F.R.S. and F.R.S. (Edinburgh), in his book, *A Clinical History of Diseases* (Vol. II, p. 155; London, 1805). The section containing the following excerpt is called "A Clinical History of the Nodosity of the Joints."

In this disease the ends of the bones, the periosteum, capsules or ligaments, which form the joint, gradually increase. These nodes are not separate tumours, but feel as if they were an enlargement of the bones themselves. . . .

The Nodes appear most nearly to resemble Gout. Both of them are attended with pain and swelling of the joints: but they differ essentially in many distinguishable circumstances. . . .

COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

The Council at its meeting May 21, 1940, directed the Committee on Medical Education and Medical Diplomas to submit to it changes in the by-laws relative to the method of admission of the graduates of unapproved medical schools to the Society. While engaged in this task the com-

*Coon, G. P., and Raymond, A. F.: *A Review of the Psychoneuroses at Stockbridge*. 299 pp. Stockbridge, Mass.: Austen Riggs Foundation, Inc., 1940.

mittee thought that certain other matters not directly in line with the above purpose, but more or less related to it, should be included in the changes to be submitted. Following are the report and recommendations as submitted to the Council at its meeting on February 5, 1941. It was decided at that meeting that the report should be printed in full with appropriate comments, so that the whole matter might be more carefully considered at a special meeting of the Council to be called for that purpose. Explanatory comments for which the chairman of the committee is solely responsible have been inserted after each suggested change in the by-laws.

* * *

For several years among the applicants for fellowship in the Society the number of graduates of medical institutions not on the list recognized by the Council has been increasing. At the present there are two groups of such graduates. One, and much the larger group, is composed chiefly of graduates of domestic institutions not recognized as medical schools by the American Medical Association. This group also includes a few American born graduates of foreign medical schools, who have studied abroad, usually because they were not accepted by any recognized domestic medical school. There are a few foreign-born, foreign educated physicians in this group who have migrated to this country, chiefly before 1937. The other group, much smaller than the first, is composed almost entirely of foreign-born graduates of foreign medical schools who are chiefly German and Jewish, but by no means exclusively either. Most of these physicians have migrated recently to this country primarily to escape political oppression. Almost without exception, they have had a good medical education and are of proved ability, often being older men of outstanding ability with international reputations.

The members of the Committee on Medical Education and Medical Diplomas are unanimous in believing that it is in the best interests of this Society to treat these two groups differently. The basis of this difference we believe should be whether or not an applicant has had an adequate medical education and enjoys a good professional reputation. With very few exceptions the members of the first group have had an inadequate education, those of the second an adequate one, and it is usually not difficult to distinguish between them. We believe that members of the first group should be admitted to membership only when there is ample positive proof that they can be regarded as truly desirable additions to the Society. At present, in

the absence of evidences of undesirability other than an inadequate medical education, they are assumed to be desirable. We cannot agree with this attitude. We believe the members of the second group should become members of the Society as soon as they have been long enough in this country to have created definite favorable opinion in the minds of colleagues whose judgment would be commonly considered valuable.

The committee has been unable under the present system to evaluate adequately the desirability for fellowship of the majority of candidates appearing before it. Repeated attempts to gather information about the prospective candidates from the officers and fellows of the district societies have usually failed. A typical situation is for an applicant who is a graduate of an unrecognized domestic school to appear before the members of the committee, who have never seen him before, but who must decide as to his desirability from his appearance, diploma, application blank and a sheaf of letters personally solicited from his medical acquaintances, who invariably say that the applicant "is a capable and conscientious practitioner of medicine" and that his practice is "ethical." Only rarely has the committee received what it regards as a confidential expression of honest intelligent opinion regarding an applicant and his work from colleagues who really know him. Part of the present functioning of the committee as dictated by the by-laws has become farcical in the minds of its members. A major change in this undesirable situation seems impossible under the present by-laws.

The Committee therefore recommends that the following changes be made in the by-laws:

1 The name of the committee be changed to the Committee on Medical Education. (*The Committee on Medical Diplomas was created in 1881 primarily to make a periodic revision of the list of medical schools recognized by the Council. The Committee on Medical Education was created in 1906 primarily to consider improvement of state laws regarding registration in medicine. The two committees were combined in 1913. The present chief function of the Committee on Medical Education and Medical Diplomas is to investigate the qualifications of applicants who are graduates of unrecognized schools. The change is recommended only in the interest of simplification.*)

2 Chapter I Section 1. In line 5 on page 9 delete the clause, that their names and addresses prior to their examination by the censors," (*This clause appears more appropriately elsewhere. See Recommendation 9.*)

3 In line 10 on page 9 omit the words, or college. (*It seems unnecessary now to use the terminology "medical school or college," though it once might have had some legal reason. The change is recommended only in the interest of simplification.*)

4. In line 14 on page 9 after "code of ethics of this Society;" insert "that they have made application according to the provisions of Chapter V, Section 2; that they have paid the examination fee of three dollars;". (*The ultimate responsibility of seeing that all new applicants comply with the various provisions for entrance into the Society should rest with the censors. Article 3 of the constitution of the Society reads in part as follows, "No person shall become a member of the Massachusetts Medical Society except upon examination by the censors of said society" The contents of these two clauses are discussed under Recommendations 9 and 8a respectively.*)

5. Chapter I, Section 6: In line 5 on page 10 substitute the word, "December," for "November." (*The date of the present fall censors' examination is the first Thursday in November. According to the new "time-table" set up under Recommendation 9 the first Thursday in December seems better, as otherwise the closing date for applications from graduates of unapproved schools falls too close to Labor Day, an admittedly poor date for district secretaries and applicants alike. No such change in the date of the spring examination is needed.*)

6. Chapter V, Section 1: Beginning at line 11 from bottom of page 16, delete the whole paragraph, "Diplomas from medical schools . . . to take an examination." (*The contents of this paragraph appear more appropriately elsewhere. See Recommendation 9. The only factual change is in the period of time.*)

7. In line 2 from bottom of page 16 substitute the word, "December," for "November." (*See Recommendation 5.*)

8. At the bottom of page 16 insert the following: (a) "A fee of three dollars shall be paid by an applicant for fellowship to the district secretary for deposit in the funds of the general Society before each examination or re-examination by the censors. (b) An applicant shall not be considered as possessing the requisite qualifications for fellowship unless approved by at least three censors. (c) An applicant failing two examinations shall be disqualified from again applying for fellowship until three years have elapsed from the date of the last application."

(a. *Examination by the censors of applicants for fellowship at present involves the applicant in no expense. The censors, however, are paid for their work, as provided for in Chapter V, Section 4, of the by-laws. In accordance with the usual custom of institutions of learning, learned societies and boards of registration in medicine everywhere it is felt that the Society should charge a fee for its examinations.*

b. *Unchanged.*

c. *If an applicant is not passed by the censors at two examinations, it is believed that some time should elapse before re-examination, so that an applicant may improve his qualifications and not appear at every examination with essentially unchanged qualifications.*)

9. Chapter V, Section 2: To read as follows:

(a) "An applicant for fellowship who is a graduate of a medical school recognized by the Council shall apply on a form furnished for the purpose to the secretary of the district in which he has legal residence, not later than March 1 for the May censors' examination or October 1 for the December censors' examination. (b) At this time the district secretary shall verify the applicant's diploma and shall deliver the application form to the Secretary of the Society not later than March 10 or October 10 respectively. (c) An applicant nonresident in Massachusetts shall apply to the secretary of the Suffolk

District Medical Society and shall be examined by the censors thereof. (d) Consideration of a late application shall be postponed until before the next succeeding examination. (e) The names of all such applicants, their addresses, medical schools, dates of graduation and the names and addresses of the various district secretaries shall be published in a list in the first number of the *New England Journal of Medicine* on or after April 1 or November 1. (f) Confidential communications regarding the qualifications of applicants for fellowship shall be requested of the fellows of the Society to be sent to the appropriate district secretary not later than April 15 or November 15.

(g) "An applicant for fellowship who is a graduate of a foreign medical school or a domestic medical school not on the list recognized by the Council or of a medical school no longer in existence, and who has practiced for a minimum of five years, shall apply for fellowship in like manner with the following exceptions and additions:

(h) "The application form must be submitted to the district secretary not later than February 15 or September 15. (i) At this time also the applicant must submit the name and address of a fellow of the Society who has agreed to act as his sponsor. (j) The sponsor's duty is to obtain from fellows of the Society who are acquainted with the applicant and his work, confidential written opinions regarding his qualifications for fellowship to be mailed directly to the district secretary not later than March 15 or October 15. (k) The application form of such an applicant shall be delivered by the district secretary to the Secretary of the Society not later than February 20 or September 20. (l) A list, similar to that of applicants who are graduates of recognized schools, but with the addition of names and addresses of sponsors shall be published in the first number of the *New England Journal of Medicine* on or after March 5 or October 5.

(m) "The president, secretary and supervising censor of the district society, sitting as a local board of membership, shall then gather such further information as is deemed necessary to determine whether an applicant is a capable and conscientious practitioner of medicine and possesses a good professional reputation among his colleagues. (n) Every candidate must be personally interviewed by this board.

(o) "The district secretary shall deliver to the chairman of the Committee on Medical Education a complete confidential file of all applications including correspondence, and the written recommendations of the local board with supporting reasons for advocating the acceptance or refusal of each applicant not later than April 1 or November 1. (p) The committee shall then determine whether or not each candidate shall be approved for examination by the censors, and shall notify the district secretary and each applicant of their decision not later than April 20 or November 20."

(a. *Provisions unchanged except for dates. The system of definite unchanging dates from year to year is utilized throughout except in the case of examination dates, rather than the present method of dating by giving the number of weeks before the examination. The present method has always caused confusion in the minds of district secretaries and applicants alike since the actual date differs each year. Dates are set so as to allow ample time for the district secretaries, the secretary of the Society, the editor of the Journal, the local boards of membership and the Committee on Medical Education to perform their duties prop-*

erly as well as to allow no misunderstanding in anyone's mind concerning the date by which certain duties should be finished. Anyone who has not been one of the above mentioned officers has difficulty in appreciating the importance of this point.

b. Transporting bulky framed diplomas to be shown to more than one official of the Society, as now accurs, is unnecessary. The Secretary of the Society has to verify and edit certain information on the application blanks before publication in the Journal.

c. Unchanged

d. Nothing is more troublesome to all the officials concerned than attempting to handle late applications, which now are submitted up to the very eve of the examination and which are always coupled with requests for special consideration.

e. Unchanged except as to dates

f. Occasionally unfavorable information of importance about an applicant exists. If it is withheld by an applicant's colleagues and an applicant is admitted to the Society, responsibility should rest on those who withheld the information. Such information when made available is always treated confidentially.

g. Unchanged in essentials

h. The difference in dates from those in a is due to the more numerous procedures required in the cases of graduates of unapproved schools.

i and j. Sponsorship of an applicant who is a graduate of an unapproved school is a new proposal. Previously the applicant always personally approached his colleagues and asked for written recommendations. This system produced recommendations some of which were retracted by their writers in separate communications, and other recommendations which were obviously written by fellows who were only casually acquainted with the applicant, and others which were refuted by other available information. It is hoped that the new system will alleviate the embarrassment of an applicant's personally asking for a recommendation from a fellow who does not feel he can honestly give it.

k. See b

l. Unchanged except as to dates

m. This change is the most fundamental of all those suggested. The Committee on Medical Education and Medical Diplomas has sensed for a long time how helpless it was in obtaining adequate information on which to determine the desirability of candidates for fellowship; this point has already been discussed more fully in the formal report. It is believed that a local board will be in every way better fitted to obtain this information than the central committee. The number of men on the board is small; they are already in positions of responsibility in their local society, and two of the three are already members of the board of censors, which eventually will examine those candidates finally approved. Further, it is very definitely felt that in the case of graduates of unrecognized schools the essential responsibility of whether or not they should be admitted to membership in the local society should lie with their own nearby colleagues, not with those farther afield. See Recommendation 11 c.

n. Unchanged, except that the interview shall be carried out by the local board rather than the central committee.

o and p. This provides that the central committee shall take the responsibility of seeing that an undue pressure has not been brought to bear on the local board

to recommend for approval an undesirable applicant, nor on the other hand has unwarranted local prejudice barred from approval a desirable applicant.)

10 Chapter V, Section 3. In line 4 on page 17 after the words, 'applicants for fellowship,' insert the clause 'they shall see that each applicant pays the examination fee.' (See Recommendation 8 a. This is inserted as it becomes a new duty for the district secretary.)

11 Chapter VII, Section 5. First two paragraphs to be changed to read as follows:

(a) "The Committee on Medical Education shall consist of five fellows. It shall consider all matters relating to medical education which may be referred to it by the Council." (b) It shall review the case of every applicant for fellowship who presents according to the provisions of Chapter V, Section 2, a diploma from a medical school not on the list recognized by the Council. (c) It shall have the power to approve for examination by the censors such an applicant, and all decisions of the committee thereon shall be final. (d) It shall revise the list of medical schools recognized by the Council whenever it appears necessary."

(a) Unchanged

b. Changed in accordance with 9 o and p

c. Unchanged

d. Changed in that previously the committee had to await direction by the Council to accomplish this duty. It is believed that this list should conform to that of the medical schools approved by the American Medical Association, which is changed from time to time. The present list dated 1934 needs sixteen changes to bring it into such conformity.)

A recent ruling by the President reversed the previous interpretation of the provisions of the by-laws regarding the application for readmission to the Society of a former fellow whose resignation had been requested by the Committee on Ethics and Discipline. Inasmuch as the individual in question was a graduate of an unrecognized school, it was ruled that he had to appear before the Committee on Medical Education and Medical Diplomas for approval, before being allowed to appear before the censors. Due to information requested from the chairman of the Committee on Ethics and Discipline, the Committee on Medical Education and Medical Diplomas disapproved the application. The latter committee, as a result of this case, believes that it should have no jurisdiction in such cases of readmission to the Society, and as a result studied the provisions of the by-laws regarding readmission. With the approval of the Committee on Ethics and Discipline and the Committee on Membership it recommends that the following changes be made in the by-laws:

12 Chapter I, Section 7. To read as follows: "The resignations of fellows whose assessments have been paid in full or remitted may, on recommendation of the Committee on Membership, be accepted by the Council and sent to the treasurer of the Society." (The sentence deal-

ing with readmission is deleted. The matter is now dealt with in Recommendation 14 a.)

13. Chapter 1, Section 8: Omit last paragraph, "Fellows who have been deprived . . . secretary of the general Society." (The sentences dealing with restoration to fellowship are deleted. The matter is now dealt with in Recommendations 14 a, b, c, d, and e.)

14. Chapter I: Add Section 10, to read as follows:

(a) "Former fellows who desire to be readmitted to the Society shall make application in writing addressed to the Council and sent to the secretary of the Society. (b) Such applications shall be referred for investigation and personal interview to the local boards of membership, which shall report their recommendations to the Committee on Membership. (c) The committee shall render the final decision as to whether to recommend to the Council the readmission of former fellows. (d) The Council shall have the power to readmit former fellows so recommended. (e) Boards having under consideration the applications of fellows whose resignations have been requested by the Committee on Ethics and Discipline, or who have been deprived of fellowship under the terms of section 8, clause (c), shall consult with the Committee on Ethics and Discipline before reporting their recommendations."

(a and b. The distinction formerly made in Chapter 1, Sections 7 and 8, between the method used in readmitting to fellowship those fellows who having "resigned" and those who having been "deprived of the privileges of fellowship" desire to rejoin the Society has been eliminated. It is believed that the local boards of membership can more adequately investigate the facts surrounding a fellow's separation from the Society and the altered situation that leads him to seek readmission than can either the censors or a specially appointed committee, as is the practice at the present.

c. The Committee on Membership should retain jurisdiction to review the recommendations of the local boards as it does at present in all cases of deprivation of fellowship. At the present it has no jurisdiction in cases of readmission to the Society following resignation.

d. The Council should have the full power of readmission of all former fellows recommended by the Committee on Membership. At present it has no jurisdiction in cases of readmission to the Society following resignation.

e. At present in cases where the Committee on Ethics and Discipline has requested a fellow's resignation as a form of discipline, and such resignation has been received, and the fellow later reapplies for readmission, the Committee on Ethics and Discipline has no jurisdiction in the matter of readmission. If the fellow in question is a graduate of an unrecognized school he must appear at present before the members of the Committee on Medical Education and Medical Diplomas, who if they approve his application pass him on to the censors for examination. This procedure is most illogical, since those who know nothing about the fellow deal with his readmission, while those who know everything about him have no official hand in the matter. At present the Council acting on separate reports of the Committee on Ethics and Discipline and of the Committee on Membership may deprive a fellow of the privileges of fellowship as provided in Chapter 1, Section 8 (c). With such a fellow desiring restoration to fellowship, a special committee is appointed to consider his case, and the by-laws provide that this committee must include at least one member of the Committee on Ethics and Discipline. The latter committee believes that

with the institution of local boards of membership consultation with the Committee on Ethics and Discipline will provide sufficient opportunity for the board to know all the facts in the case before reporting its recommendations.)

JOHN P. MONKS, Chairman

* * *

For comparison, the by-laws referred to above are printed as they now stand:

CHAPTER I

FELLOWSHIP

Section 1. Applicants for admission to fellowship in the Massachusetts Medical Society are required to satisfy the censors that they are not less than twenty-one years of age; that they are of sound mind and of good moral character; that they possess a good English education that their names and addresses and the name and address of the secretary of the district society in which they reside have been published in a special list in the *New England Journal of Medicine* at least two weeks prior to their examination by the censors; that they have received a diploma from a medical school or college recognized by the Council, or that they have, in each instance, received the approval of the Committee on Medical Education and Medical Diplomas; that they do not practice medicine in a manner contrary to the code of ethics of this Society and they shall appear personally before the censors and satisfy them that the above requirements are fulfilled.

Section 6. Fellows shall be assessed annually such sum as the Council may determine. The fiscal year shall begin on the first day of January. Assessments shall be payable in advance. The first assessment paid by a fellow admitted to the Society following the November examinations shall cover his dues for the succeeding fiscal year and shall be the amount fixed for that year.

Assessments may be remitted by the Council on recommendation by the Committee on Membership.

Whenever a fellow owing more than one annual assessment pays for one year or more, the payment or payments so made shall be considered as for the assessment or assessments longest due, and for no others.

Section 7. The resignations of fellows whose assessments have been paid in full, or remitted, may, on recommendation of the Committee on Membership, be accepted by the Council. Should such fellows apply for readmission, they shall appear personally before the censors and the censors shall satisfy themselves that such applicants still meet the requirements of sections 1 and 2 of chapter I. Petitions to be allowed to resign should be addressed to the Council and sent to the Treasurer of the general Society.

Section 8. (a) Resident fellows who have neglected payment of three annual assessments, and who continue to neglect payment after notification by the Treasurer shall be deprived of the privileges of fellowship, unless otherwise ordered, by the Council acting on a report of the Committee on Membership.

(b) Non-resident fellows who have neglected payment of two annual assessments, after removal from the state shall be deprived of the privileges of fellowship in the same manner.

(c) Fellows who have been convicted in a court of law of a crime or misdemeanor involving moral turpitude or

who have been deprived of license to practice medicine in the Commonwealth, may be deprived of the privileges of fellowship by the Council acting on separate reports of the Committee on Ethics and Discipline and of the Committee on Membership, presented by the latter committee. Before a fellow shall be so recommended for deprivation, he shall have the privilege, if he requests it in writing, of a hearing by the joint committee.

Fellows who have been deprived of the privileges of fellowship and desire restoration shall make application in writing to the Council. Such application shall be referred to a committee for investigation and report. A committee having under consideration the application of a fellow deprived of the privileges of fellowship under the terms of clause (c) shall include in its membership at least one member of the Committee on Ethics and Discipline. All applications shall be addressed to the Council and sent to the Secretary of the general Society.

CHAPTER V

CENSORS AND SUPERVISORS

Section 1 The supervisors, representing the censors of the several district societies, shall constitute a board, which shall meet annually on the day appointed for the annual meeting of the Council. The board shall elect a chairman, who shall have power to call special meetings. Five supervisors shall constitute a quorum. The Secretary of the general Society shall act as secretary of the board. He shall call special meetings at the request of five supervisors. He shall keep a permanent record of the proceedings of the board, and shall provide, at the expense of the Society, papers and forms necessary for conducting examinations of applicants for fellowship. The board at its annual meeting shall adopt a uniform plan for the examination of applicants. The supervisors shall be paid the amount of their traveling expenses from the funds of the Society.

The supervisors shall be chairmen of their respective boards of censors, and shall cause the examinations of applicants to be conducted in strict conformity to the plan adopted by the Board of Supervisors.

Diplomas from medical schools and colleges no longer in existence, and diplomas from all foreign and domestic medical schools which are not on the list of medical schools and colleges recognized by the Council, shall be referred to the Committee on Medical Education and Medical Diplomas by the district secretary three weeks before an applicant shall be permitted to take an examination.

The censors of the several district societies shall meet semi-annually for the examination of applicants on the first Thursday in May and on the first Thursday in November. Special meetings may be held by order of the Council.

Section 2 An applicant for fellowship who is a graduate of a medical school or college recognized by the Council, shall apply, on a form furnished for the purpose to the secretary of the district in which he has a legal residence, at least six weeks before the date of a given examination. Applicants who are graduates from medical schools or colleges not upon the list recognized by the Council, shall apply not later than eight weeks before the time of a given examination. An applicant non-resident in Massachusetts shall apply to the secretary of the Suffolk District Medical Society, and shall be examined by the censors thereof. An applicant shall not be considered as possessing the requisite qualifications for fellowship unless approved by at least three censors.

Section 3 District secretaries, who shall act also as secretaries of their respective boards of censors, shall furnish applicants with forms adopted by the Board of Supervisors, they shall keep a complete record of all applicants for fellowship, they shall see that each successful applicant subscribes to the bylaws and code of ethics and pays within two weeks the dues for the current year, they shall furnish each new fellow with a copy of the digest, by laws, code of ethics, and Medical Defense Act of the Society, and they shall present promptly after each examination, to the Treasurer of the general Society on a blank form furnished by him, a bill for censors' services together with a list of all the applicants examined. (See also chapter III, section 7.)

Following the examination of applicants, the district secretaries shall fill out, sign, and forward promptly to the Secretary of the general Society certificates stating that the successful applicants have complied with the requirements of the bylaws.

CHAPTER VII

Section 5 The Committee on Medical Education and Medical Diplomas shall consist of five fellows. It shall consider all matters relating to medical education which may be referred to it by the Council. When directed by the Council it shall revise the list of medical schools and colleges recognized by that body. Questions as to diplomas, referred to the censors under the provisions of chapter V, section 1, shall receive consideration and the decisions of the committee thereon shall be final.

It shall have power to recognize a medical diploma from a foreign medical school or college or from a domestic school or college not on the list recognized by the Council, when such a diploma is presented by an applicant who has practiced for a minimum of five years, offers proof to the committee that he is a capable and conscientious practitioner of medicine, and is recommended in confidential communications by a number of his colleagues who are fellows of the Society. The medical diploma and written recommendations of colleagues shall be sent by the district secretary to the chairman of the committee at least three weeks before any given examination. The committee shall interview personally all such applicants for fellowship.

It shall make a report to the annual meeting of the Council. On or before the fifteenth of January annually, it shall forward to the chairman of the Committee on Financial Planning and Budget an estimate of the expenses for the current year. All bills incurred shall be countersigned by the chairman and forwarded to the President for his approval.

COMMITTEE TO CONSIDER NEW OFFICERS AND BY-LAWS

Following the Council meeting of October 2, 1940, a committee was appointed by the president of the Massachusetts Medical Society to study the desirability of establishing the offices of president-elect and full-time or executive secretary and to suggest the necessary changes in the bylaws required to create these positions. At the Council meeting of February 5, 1941, the bylaws dealing with the creation of the office of president-elect

were accepted. At the same meeting the plan of having an executive secretary was accepted in principle, but the manner of electing the executive secretary was left to be determined.

At the Council meeting of October 2, 1940, a motion was made that this same committee should study the possibility of redistricting the Massachusetts Medical Society, with the idea of harmonizing its set-up with that of the American Medical Association and other state societies. The committee, in reporting at the Council meeting of February 5, 1941, took no action in respect to the problem of redistricting, but did suggest certain by-laws by which an executive committee of the Council could be established. In respect to the latter, the Council voted "that the committee continue and that it explore the possibilities of an executive committee so constituted that each district medical society would be represented."

Hence, your chairman has circularized the secretaries of the different district societies, asking them to secure, if possible, in the brief time between Council meetings, an opinion from their respective districts as to the best method of selecting an executive committee of the Council, and the possibility of redistricting the Massachusetts Medical Society.

In one way or another, your chairman has heard from six secretaries and from various sources has received the following impression: that no district desires a change in its boundaries and that a majority of the districts are opposed to such a change; that the idea of an executive committee of the Council is generally acceptable and that the districts prefer that each of them should be represented on this committee, no others to be made members of the committee except the officers of the Society. In accordance with this understanding, your committee, after consulting together, suggests the following changes in the by-laws.

JOHN HOMANS, *Chairman*,
JOHN FALLON,
PEIRCE H. LEAVITT,
FRANK R. OBER,
WALTER G. PHIPPEN, *ex officio*,
AUGUSTUS THORNDIKE, JR.

CHAPTER III DISTRICT SOCIETIES

Section 5. (Additional)

The councilors of each district society shall meet immediately after the annual meeting of the district society in 1941 and elect one of their number to serve as a member of the Executive Committee of the Council in accordance with Chapter IV, Section 10. Thereafter, in a similar manner, they shall elect a new member from time to time.

Section 7. (Additional)

The secretary of each district society immediately after the annual meeting of the district society in 1941 shall call together its councilors for the purpose of electing a member of the Executive Committee of the Council and shall send the name of the member chosen to the Secretary of the general Society. He shall see that a new member is chosen in a similar manner to fill a vacancy as it occurs, in accordance with Chapter IV, Section 10.

CHAPTER IV

THE COUNCIL

Section 10. The Executive Committee shall consist of the President, President-Elect, Vice-President, Secretary and Treasurer *ex officio*, and a councilor from each district medical society chosen in accordance with Chapter III, Section 5. The election of a councilor to the Executive Committee of the Council shall not be considered as leaving a vacancy among the councilors from the district he represents.

The councilors of each district society shall meet immediately after its annual meeting in 1941, as specified in Chapter III, Section 5, and in a similar manner at stated intervals as specified below, to choose one of their number to serve as a member of the Executive Committee of the Council.

A member of the Executive Committee shall serve for three years and shall not be eligible for re-election before the expiration of three years following the conclusion of his term of office; except that in 1941 six members shall be selected by lot to serve one year, six members shall be selected by lot to serve two years and six members shall be selected by lot to serve three years. Thereafter, six members shall be elected every year to succeed in office those whose terms are about to expire.

The Executive Committee shall meet at the call of the President at least once in each interval between Council meetings and may meet more often at the pleasure of the President. It shall assist the President in preparing for the consideration of the Council matters calling for action by the Council at its next meeting. It shall authorize action by the officers of the Society when circumstances require it, subject to the approval of the Council. It shall perform such other duties as the Council may require.

The consent of the Executive Committee shall be required to confirm the appointment, upon nomination by the President, of the Executive Secretary of the Society.

Upon request, members of the Executive Committee shall be paid the amount of their traveling expenses from the funds of the Society.

CHAPTER V

CENSORS AND SUPERVISORS

Section 1. The supervisors, representing the censors of the several district societies, shall constitute a board, which shall meet annually on the day appointed for the annual meeting of the Council. The board shall elect a chairman, who shall have power to call special meetings. Five supervisors shall constitute a quorum. The Secretary or Executive Secretary of the general Society shall act as secretary of the board. He shall call special meetings at the request of five supervisors. He shall keep a permanent record of the proceedings of the board, and shall provide, at the expense of the Society, papers and forms necessary for conducting examinations of applicants for fellowship. The board at its annual meeting shall adopt a uniform plan for the examination of applicants. The

supervisors shall be paid the amount of their traveling expenses from the funds of the Society

CHAPTER VI

OFFICERS

Section 1 (Additional)

He shall call at least one meeting of the Executive Committee of the Council between Council meetings and may call more meetings if he so desires

Section 4 The Secretary may assign to an Executive Secretary any or all the duties now to be enumerated, except as specified below

The Secretary shall attend all meetings of the Society and of the Council, and shall record their respective proceedings in separate record books, and this duty he may not assign

He shall cause to be engrossed and shall sign the diplomas of new fellows if satisfied that they have met the requirements of Sections 1 and 2 of Chapter I, and shall issue all diplomas and certificates of fellowship. He shall notify individual fellows, in appropriate instances, of votes by the Council granting permission, as the case may be, to retire, to resign, to change district membership, to have dues remitted, or of votes depriving them of the privileges of fellowship, and these duties he may not assign

He shall act *ex officio* as secretary of all boards of trial, and this duty he may not assign

He shall have custody of the seal of the Society and of all books, papers, manuscripts, prints and paintings belonging to the Society, except such as are in charge of the Treasurer, and this duty he may not assign

He shall act *ex officio* as secretary of the Board of Supervisors and of the Committee on Publications and the Committee on Ethics and Discipline, and shall keep the records of each in a separate volume. He shall have custody of all records as thus kept.

He shall issue notices of the meetings of the Council One month before the annual meeting of the Society, he shall issue to every fellow a program, which shall contain notification of the time and place of the annual meeting, notification of the stated meetings of the Council for the year and the meetings of the boards of censors, and information concerning the payment of assessments and the distribution of publications

He shall record the Proceedings of the Council and of the Society. He shall keep a complete list of the fellows of the Society, with their addresses so far as known. He shall transfer fellows from one district to another under the terms of Chapter III, Section 2, and shall report to the Society at its annual meeting the changes in membership of the Society during the year

He shall conduct the official correspondence of the Society, and shall notify officers, delegates and members of the committees of the general Society of their appointments and of their duties

Under the direction of the Committee on Publications he shall issue at such intervals as may be determined by the Council a directory of officers and fellows of the Society, which shall be furnished upon request to fellows who are not in arrears

He shall perform such other duties as the Society or the Council may require

Section 5 An Executive Secretary shall be chosen by the Executive Committee of the Council upon nomination by the President. He shall hold office until his successor has been duly elected

He shall perform such duties as are assigned to him

in Section 4 of this chapter and by the Executive Committee. In general, he shall assist the officers of the Society and such standing and other committees as may request his services, and the Society shall have the first call upon his services

He shall attend all meetings of the Council and, on request, attend the meetings of the Executive Committee of the Council, but shall not vote in either

An Executive Secretary need not be a physician

COMMITTEE ON STATE AND NATIONAL LEGISLATION

The following bills are scheduled for hearings at the State House during the week of March 31

April 3

H 1223 (Public Health) Petition of the Massachusetts Central Health Council and another for legislation to authorize the treatment of spastic paralysis at the Lakeville State Sanatorium. The committee believes that the Lakeville State Sanatorium is intended only for cases of nonpulmonary tuberculosis. *Opposed*

H 869 (Public Health) Petition of Enrico Cappucci and Lawrence P. McHugh for the suspension of the license of physicians who fail to make public their insurance company connections. This bill requires further investigation. *Undecided*

H 2007 (Public Health) Petition of Catherine E. Falvey for the establishment of a bureau for the care of inebriates under the Department of Public Health and relative to the powers and duties of such bureau. *Undecided*

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., Secretary
330 Dartmouth Street
Boston

PERNICIOUS VOMITING IN PREGNANCY WITH FATAL OUTCOME

A thirty three year-old essential multipara in her fourth pregnancy was first seen when she was about ten weeks pregnant. She had been vomiting for two or three weeks before she consulted the doctor, and she was treated at home for two weeks before hospitalization.

The three previous pregnancies had resulted in a miscarriage at about eleven weeks, a spontaneous delivery at five months and a spontaneous delivery at six months. She had had no serious illness.

At the first examination the heart was not enlarged; there were no murmurs. The lungs were clear and resonant, there were no rales. The abdomen was negative except for a uterus that was enlarged to a size consistent with the period of amenorrhea. A blood Wassermann reaction was negative. The patient complained of vomiting of two to three weeks' duration.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

After a period of two weeks of inadequate medical treatment at home, the patient was sent to the hospital. On admission she was dehydrated. The tongue was dry and coated. The blood pressure was normal. The uterus was enlarged and in a normal anterior position.

For twelve days the patient was treated intensively with intravenous glucose, sedation and gastric feedings. On the thirteenth day after admission, she developed cerebral symptoms. On investigation by a consultant these were diagnosed as cerebral edema. The condition did not improve, and the patient died without operation on the twenty-fifth day after hospitalization.

Autopsy revealed a three months' pregnancy; nephrosis; acute venous congestion of the lungs and spleen with hemorrhage; edema of the brain, optic nerve and retinas; strangulation of the appendices epiploicae (torsion of pedicle); petechial hemorrhages in the epicardium and the mucosa of the stomach.

Comment. It is interesting in reviewing this history to note that the patient had three previous pregnancies but no living children. It is perfectly possible that the two pregnancies that ended spontaneously at five and six months respectively may have been induced by an underlying malnutrition. It is uncommon for patients exhibiting severe symptoms from vomiting in early pregnancy not to respond to intravenous glucose, sedation, gastric feedings and concentrated intramuscular injections of vitamin B. The unusual patient under this treatment continues to vomit and lose weight, shows increasingly rapid pulse and may develop jaundice. These symptoms demand medically that the uterus be emptied. Fortunately, therapeutic abortion for pernicious vomiting of pregnancy is extremely uncommon when the patients are treated adequately.

REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1941.

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 4, to be counted for the refund, was, 4038. Therefore the refund to the district societies for each paid fellow is \$0.99.

The following table gives the number of payments in, and the refund to, each district as of March 18:

DISTRICT	NUMBER REPORTED PAID	REFUND
Barnstable	36	\$36.12
Berkshire	109	107.91
Bristol North.....	65	64.83
Bristol South.....	158	156.42
Essex North	172	170.28
Essex South	242	239.58
Franklin	40	40.08
Hampden	299	296.01
Hampshire	50	49.98
Middlesex East	114	112.86
Middlesex North	103	101.97
Middlesex South	762	754.38
Norfolk	703	695.97
Norfolk South.....	120	118.80
Plymouth	117	115.83
Suffolk	521	515.79
Worcester	344	340.56
Worcester North.....	83	82.63
	4038	\$4000.00

In 1940, for comparison, the total number of payments for the refund was 4058.

CHARLES S. BUTLER, M.D., *Treasurer.*

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 30:

BERKSHIRE

Thursday, April 3, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. Diagnosis, Treatment and Prognosis of Central-Nervous-System Syphilis. Instructor: Francis M. Thurmon. Harry G. Mellen, *Chairman.*

BRISTOL SOUTH (Fall River Section)

Tuesday, April 1, at 4:30 p.m., at the Union Hospital, Fall River. Acute Abdominal Pain: Its interpretation and management. Instructor: Richard B. Cattell. Howard P. Sawyer, *Chairman.*

FRANKLIN

Thursday, April 3, at 8:00 p.m., in the Library of the Franklin County Public Hospital, Greenfield. Recent Advances in Medical Therapeutics. Instructor: Charles L. Short. Halbert G. Stetson, *Chairman.*

HAMPDEN

Wednesday, April 2, at 4:00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p.m., in the Out-patient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Dermatitis and Eczema. Instructor: John G. Downing. Alfonso A. Palermo, *Chairman.*

PSHIRE

Thursday, April 3, at 4 15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton Pediatric Case Discussions Instructor James M Baty Robert C Byrne *Chairman*

ESTER

Tuesday, April 1, at 8 30 p.m., in the Nurses' Home of the Milford Hospital, Milford Therapeutic Uses of Preparations of Endocrine Glands Thyroid gland, pituitary gland, ovary, testis and adrenal cortex Instructor William T Salter Joseph Ashkins, *Chairman*

ESTER NORTH

Friday, April 4, at 4 30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg The Treatment of Varicose Veins Instructor F Everett O'Neil George P Keaveny, *Chairman*

TH

ASON—GILBERT McC MASON, MD, of Dorches died March 17 He was in his seventieth year When in Clinton, he attended Cushing Academy and received his degree from Boston University School of Medicine in 1898 From 1901 to 1910 he was demonstrator in anatomy at Boston University School of Medicine and also served on the staffs of the Carney and Forest hospitals. Dr Mason was a fellow of the Massachusetts Medical Society and the American Medical Association, as well as a member of the Association of Military Surgeons and the American Institute of Homeopathy He was a widower, a daughter, two brothers and two sisters survive him

NOTES

Dr Elkhott P Joslin was the speaker at the meeting of the Osler Clinical Society of the University of Vermont College of Medicine on Wednesday evening, March 12 The subject of Dr Joslin's lecture was 'The Application of Recent Physiological Studies to the Treatment of Diabetes Mellitus'

Harvard University recently announced the appointment of Dr William C Quinby as clinical professor of genitourinary surgery, emeritus and Dr Irving J Walker as clinical professor of surgery, emeritus, on the faculty of Harvard Medical School to become effective September 1

CORRESPONDENCE

MEDICAL CONTRACEPTIVE CARE

To the Editor The public hearing on House 2035, the Massachusetts initiative petition for 'an act to allow physicians to provide medical contraceptive care to married persons for the protection of life or health, will be held before the Committee on Public Health of the Legislature at 10 30 a.m., Thursday, April 3, in the Gardner Auditorium, State House, Boston

The petition, which was initiated by ten prominent citizens of Massachusetts, including Drs Nathaniel W Faxon, of Newton, Frederick C Irving of Brookline, John C Rock, of Boston, and Curtis C Tripp, of New Bedford, was filed with 44,565 certified signatures of registered Massachusetts voters more than double the 20,000 signatures required by law

The petition is supported by the Committee for the Defense of Medical Rights, which reports that a majority of active members of the Massachusetts Medical Society have signed statements in support of the principle that physicians should be exempted from the restrictions of the present law

Adoption by the Legislature of the proposed act would amend Chapter 272 of the General Laws by adding at the end of Section 21, the following:

The provisions of this section and of section twenty which relate to the prevention of pregnancy and the prevention of conception shall not apply to treatment or prescription given to married persons for protection of life or health by or under the direction of physicians registered in accordance with the provisions of Chapter 112; nor to teaching in chartered medical schools; nor to publication or sale of medical treatises or journals.

Only Massachusetts and Connecticut have laws that have been enforced in such a way as to interfere with the right of a physician to prescribe contraceptives to a married woman for health reasons. Three states—North Carolina, South Carolina and Alabama—have incorporated postnatal contraceptive care into their maternal-health programs under the direction of their respective state medical societies.

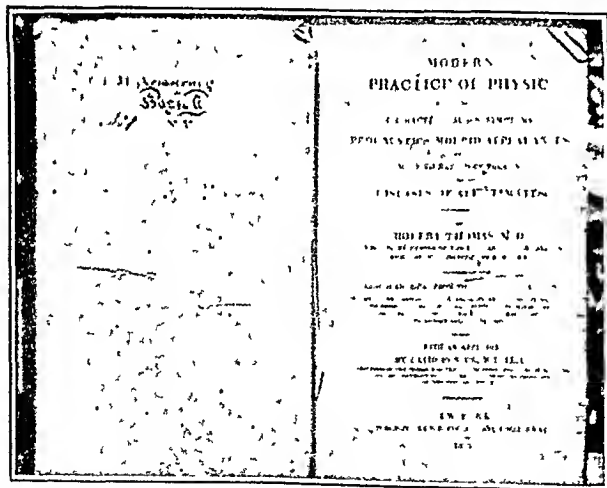

WILLIAM H. ROBEY, M.D., *President*,
Committee for the Defense of Medical Rights.

270 Commonwealth Avenue,
Boston.

DR. P. M. ARMSTRONG,
OF HOOSICK, NEW YORK

To the Editor: A rather peculiar incident occurred to me recently. I was reading the June, 1939, issue of *Digest of Treatment* and noted a "Tombstone Inscription in Hoosick, N. Y." taken from the *New England Journal of Medicine*.

At first the name Dr. P. M. Armstrong did not register, but later I remembered that about fifteen years ago

a Mr. Armstrong gave me an old volume which had been his grandfather's and had been kept in the family for many years. This volume, *The Modern Practice of Physic*, by Robert Thomas, published in New York in 1825 by S. B. Collins, and Collins and Company, and marked number one volume from the library of P. M. Armstrong, of Hoosick, New York, evidently belonged to the person referred to in the inscription.

ARTHUR H. STOLL, M.D.

329 North Fifth Street,
Oxnard, California.

The tombstone inscription referred to above is as follows:

RUTH SPRAGUE

dau. of Gibson
& Elizabeth Sprague,
died Jan. 11, 1846; aged
9 years 4 mo's & 3 days.

She was stolen from the grave
by Roderick R. Clow & dissected
at Dr. P. M. Armstrong's office
in Hoosick N. Y. from which place
her mutilated remains were
obtained & deposited here.

Her body dissected by fiendish Men
Her bones anatomised,
Her soul we trust has risen to God,
Where few Physicians rise.

It was contained in a letter, "Body Snatching," submitted by Dr. Edward F. Timmins, of South Boston, and published in the March 16, 1939, issue of the *Journal*. Ed.

RESTORATION OF LICENSE

To the Editor: At the meeting of the Board of Registration in Medicine held March 13, there was restored to Dr. Michael Litvich, 114 Shirley Avenue, Revere, Massachusetts, his license, which had been revoked on December 19, 1940.

STEPHEN RUSHMORE, M.D., *Secretary*,
Board of Registration in Medicine

State House,
Boston.

REVOCATION OF LICENSE

To the Editor: The license of Dr. Claude G. Shepherd, formerly of 84 Humboldt Avenue, Roxbury, Massachusetts, was revoked by the Board of Registration in Medicine on March 13 because of violation of the law concerning narcotic drugs.

STEPHEN RUSHMORE, M.D., *Secretary*,
Board of Registration in Medicine

State House,
Boston.

NOTICES

MEDICAL AND SURGICAL SUPPLY COMMITTEE

It will help England greatly in the care of victims of bombing raids and help England prepare for the coming invasion, if physicians in this country will give discarded or superfluous surgical instruments or surgical dressings.

Any such material should be sent to the Medical and Surgical Supply Committee, 420 Lexington Avenue, New York City.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater on Tuesday, April 8, at 8:15 p.m.

PROGRAM

Presentation of cases.
Disabilities in Reading and Their Remedying. Professor Walter F. Dearborn, Harvard University.

JOSEPH H PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a m

MEDICAL CONFERENCE PROGRAM, APRIL

- Tuesday, April 1—Cell Respiration Dr W Gleim
Thursday, April 3—Vitamin B Deficiency (motion picture film)
Friday, April 4—Mental Changes in Paget's Disease Dr R C Wadsworth
Tuesday, April 8—Pancytopenia Drs William Damshek and E B Miller
Thursday, April 10—The Problem of Vasomotor Rhinitis Dr L R Weiss
Friday, April 11—Certain Aspects in the Diagnosis and Treatment of Contagious Diseases Dr E H Place
Tuesday, April 15—Medical Ophthalmology Dr S T Clarke
Thursday, April 17—Endocrinological Relation between the Hypophysis and the Eye Problems and facts Dr J Igersheimer
Friday, April 18—What Happens to Alcoholics Dr Merrill Moore
Tuesday, April 29—Sir Charles Bell in Modern Dress Dr Leonard Carmichael

Morning conferences will be suspended for the week of April 21, during the meetings of the American College of Physicians

On Wednesday and Saturday mornings throughout the month Dr S J Thannhauser will give a medical clinic on hospital patients

BOSTON SOCIETY OF BIOLOGISTS

There will be a meeting of the Boston Society of Biologists at the Harvard Medical School Amphitheater E, on Wednesday, April 30, at 8 p m

PROGRAM

- Chemical Conjugation of Antibodies without Destruction of Their Function Dr Alvert H Coons
Production of a Condition Resembling Typhoid Fever by Means of a Purified Antigen of the Typhoid Bacillus Mr Herbert R Morgan, A M
Results Obtained in a Laboratory Study of the Recent Epidemic of Influenza Dr John F Enders
The Production of Tetanus Toxin on a Peptone Free Medium Dr J Howard Mueller
Dinner will be served in the main dining room of Vanderbilt Hall, Harvard Medical School at 7 p m
The rules of the dormitory do not permit the attendance of ladies at the dinner
Reservations should be made not later than Monday, April 28

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

A business meeting of the Massachusetts Public Health Association will be held at the time of the New England Health Institute on Thursday, April 3, in Parlor A Hotel Statler Boston at 1 p m

SALEM TUMOR CLINIC

A teaching clinic on chronic cystic mastitis, to be followed by the presentation of cases of breast disease will be held at the Salem Hospital on Friday April 25, at 9 a m
The clinic will be conducted by Dr Shields Warren
Members of the Massachusetts Medical Society are cordially invited to attend

WACHUSETT MEDICAL IMPROVEMENT SOCIETY

The next meeting of the Wachusett Medical Improvement Society will be held at the Holden District Hospital on Wednesday, April 2, at 6 30 p m Dr Foster L Vibber, of Worcester, will speak on 'A Practical Application in Neurology and Psychiatry'

AMERICAN PUBLIC HEALTH ASSOCIATION

The seventeenth annual meeting of the American Public Health Association will be held in Atlantic City, New Jersey, from October 14 to 17
The American School Health Association, the Association of Women in Public Health, the National Organization for Public Health Nursing, the International Society of Medical Health Officers, the New Jersey Health and Sanitary Association, the American Social Hygiene Association, the Conference of State Sanitary Engineers, the Conference of Municipal Public Health Engineers, the Conference of State and Provincial Public Health Laboratory Directors, the Conference of State Directors of Local Health Administration and the Conference of Pneumonia Control Officers will meet in conjunction with the association

It will bring 4000 public health workers to Atlantic City for a series of scientific meetings covering all phases of health protection and promotion
For further information address the American Public Health Association 1790 Broadway at 58th Street New York City

AMERICAN ACADEMY OF PHYSICAL MEDICINE

The nineteenth annual meeting and scientific session of the American Academy of Physical Medicine will be held in New York City, April 28 29 and 30
The headquarters will be at the Hotel Pennsylvania where lectures symposiums clinical papers motion pictures and exhibits will be presented with clinics at the Medical Center New York Orthopaedic Hospital Post Graduate Hospital and the Skin and Cancer Hospital
There will be an evening session at the Academy of Medicine and a banquet at the Hotel Pennsylvania

The scientific program will be open to the medical profession without registration fee
For further information write to Dr Herman A Osgood Secretary, 144 Commonwealth Avenue Boston

BOOK REVIEWS

The Early Diagnosis of the Acute Abdomen. By Zachary Cope, A.B., M.D., M.S. (Lond.), F.R.C.S. (Eng.). Eighth edition. 8°, cloth, 257 pp., with 36 illustrations. London: Oxford University Press, 1940. \$3.75.

This handy volume is essentially a diagnostic primer. Its value lies in its simplicity and proper emphasis of well-established facts rather than in any new analysis of symptoms or signs. The author stresses continually the need for accurate diagnosis in patients with acute abdominal symptoms. To accomplish this it is necessary to take a very careful history and to make a thorough physical examination. The urinary and blood findings are valu-

able supplementary data, although the author says little about the white-blood-cell count and nothing about the value of a differential count of the white blood cells.

In no other group of cases is judgment at a greater premium than in the diagnosis of acute surgical conditions of the abdomen. Such patients often enter in the early morning hours; they present the problem of pain that must be relieved; and on the basis of a few available facts one must decide whether operation is necessary and, if so, where the incision should be made. Cope has ably summarized the classic pictures, and has also indicated some of the leads that show the way when the picture is very confusing. The intangibles that cannot properly be put in writing and that must be interpreted can be mastered only through study of and experience with patients. Is spasm voluntary or involuntary? Are signs at the base of the right lung primary, or secondary to abdominal disease? Are the urinary findings due to a pelvic appendix? The answers to questions such as these rest entirely on judgment and experience.

To the medical students in this country and abroad this volume will be a great friend in guiding them through the intricacies and pitfalls of diagnosis in acute abdominal conditions. This new edition offers only slight change from the previous ones.

Manual of Cardiology: Clinical methods and case histories as problems for study. By William Duncan Reid, A.B. M.D. 8°, cloth, 364 pp. London: Oxford University Press, 1940. \$3.50.

The first one hundred and thirty-five pages of this book describe the clinical methods of the author. The rest of the book is concerned with a description of a series of fifty-six case histories followed in a separate section by discussions of the cases. The author admits that "the language of Section I is purposely very informal," but although this may serve his purpose of making "the text easier to read and more forceful," it creates an impression of carelessness. This is added to by the various errors in spelling and syntax, and the irritatingly poor proofreading. It seems unnecessary to mention the very unimportant signs of Duroziez and Graham Steell in a book of this sort, doubly so when the names are misspelled on each occasion.

Much of the discussion of clinical methods will be useful for the undergraduate student, and since the book is not intended as a textbook, it should not be too harshly judged by its omissions. Some rather obvious ones, however, may be noted, such as the failure to mention pulmonary infarct as the commonest cause of jaundice in cardiac patients, the inadequate description of the mechanism of gallop rhythm that is such an important physical sign, and the omissions of venesection in the treatment of acute pulmonary edema and of oxygen in acute coronary occlusion or cardiac failure.

The method of presentation by case histories of the material in Sections II and III has become established as a valuable technic. The case reports are, at times, instructive, but often one is asked to consider the diagnosis on the basis of inaccurate observations purposely given to indicate the errors of examination. It is questionable if this teaches anything except to mistrust all examinations save one's own. It is used by the author, for example, to illustrate errors in the diagnosis of the presystolic murmur that his colleagues seem so often to have found without anatomic basis. The discussion of this murmur is rather naïve in the light of present knowledge of the mechanism of heart sounds and murmurs.

the diagnosis of some of the cases may be questioned. For example, Case 28 is considered pulmonary stenosis and entricular septal defect. In the absence of cyanosis of the fingers, this seems unlikely. A septal defect is more probable.

The book will teach the beginner many practical points, and the case reports are a stimulus to diagnosis. The chief value of the book is in emphasizing methods of approach to clinical problems, and it should be helpful mainly for graduate instruction.

Management of the Cardiac Patient By William G. Lea, Jr. M.D. 8°, cloth, 705 pp., with 255 original illustrations, two in color, 29 tables. Philadelphia: J. B. Lippincott Company, 1940. \$6.50.

Progress in modern medicine is advancing at so rapid a pace that it is impossible for the general practitioner or internist to keep abreast of the entire current literature in one field. The author of a good textbook is eager of this rich harvest, he must also select the cream of the chaff. Dr. Leaman has succeeded in assembling in one volume most of the essential facts in the management of the cardiac patient. In the twenty-four chapters of this book are included most of the types of disease that are commonly met in the clinic and hospital.

Since modern cardiology is dynamic rather than static—that is, emphasis is laid on the etiology of the disease and the functional capacity of the patient, rather than on the description of the structural defect—the author proceeds from that point of view. Each chapter is a theoretical exposition, just long enough to cover essential facts, and short enough to hold the reader's interest. Variations that occur in the different types of disease are also considered. The book is up to date in that it includes most of the recent advances made in cardiology. There is a brief discussion of total ablation of the thyroid gland in selected cases of patients suffering from congestive cardiac failure or angina pectoris, published in 1933, as well as the latest Boston contribution—Crosby operation for the ligation of the arteriovenous anastomosis in patent ductus arteriosus. Each chapter ends with a number of illustrative cases. The book contains numerous original illustrations, two of which are in color. These help to clarify a complicated subject. It is gratifying, indeed, that during these days of scientific medical research, but also in making this volume available to many by textbooks as fine as one.

Diseases of Infancy and Childhood A textbook for use of students and practitioners. By the late L. Emmet Holt, M.D., and John Howland, M.D. Revised by Emmet Holt, Jr., M.D., and Rustin McIntosh, M.D. Tenth edition. 4°, cloth, 1421 pp., with 262 illustrations and 8 plates. New York: D. Appleton Century Company, Incorporated, 1940. \$10.00.

For many years Dr. Holt's book stood as the bible of pediatricians in the United States. Its status paralleled that of the *Principles of Medicine*, every doctor knew it and every doctor owned it. With the passing of Dr. Holt and of Dr. Howland, who had collaborated with him in the distinctive personal touch naturally departed, but his last analysis the loss was largely sentimental. In three successive editions for which the new authors are responsible, they have improved increasingly their clinical abilities. Although the title page speaks of revision, more than revision has been done. They have

emerged with a new book, and Holt much better, in certain respects, than the old one ever was.

It covers a great deal more ground. Originally, as the title implied, the book was almost wholly concerned with the child in sickness. Now, and to a greater extent in this edition than in its immediate predecessors, much space has been given to hygiene, nutrition, growth and feeding. But there is still further departure in this latest issue. Because the general subject has so grown and because within the specialty new specialties have arisen, thirty-four subsidiary authors have been requisitioned for contributions. Such a move, we grant, is not always happy in its results, too often the disadvantages outweigh the benefits. A multiplicity of authors commonly means a multiplicity of points of view, an uneven scale of values and emphases. But teamwork has prevailed, and the unity of the book has not been appreciably disturbed. One might almost have anticipated which sections would require the greatest changes—those relating to diseases of the newborn, nutrition, allergy, endocrinology, the deficiency diseases, the diseases of the blood and some of the specific infections. These have been expanded, and although in previous editions the material at times has been compressed to keep the general bulk within bounds, this eleventh edition runs two hundred pages longer than the tenth. It should be added that there is an entirely new section on diseases of the eye, some of the pictures are different, and there are some new charts.

The more one studies this book, section by section, the more one is likely to be impressed. Apparently there are no significant omissions, and there is a gratifying sense of proportion and balance. If the facts are up to the minute, so too is the point of view. There are excellent bibliographies. The publisher has also done his part, in format, in printing and in clarity of illustration. This book leaves little to be desired.

It may not be the old familiar Holt, it may not be indispensable. But it is nevertheless an outstanding book, one that can be trusted and valued and repeatedly used.

The Individual and his Society: The psychodynamics of primitive social organization By Abram Kardiner, M.D. With a foreword and two ethnological reports by Ralph Linton. 8°, cloth, 503 pp. New York: Columbia University Press, 1939. \$3.50.

Although this book will be of little interest to the general practitioner, it doubtless has value for the psychiatrist and psychoanalyst interested in reading on the periphery of their subjects. It also has a certain value for sociologists who are not impatient with such ultra abstract attempts to co-ordinate anthropology, sociology, psychology and psychoanalysis.

Dr. Kardiner is a practicing psychiatrist. The material in this book is the product of a seminar held at the New York Psychoanalytic Institute over a period of three years. Although the main body of the material is an ethnological, eight primitive cultures having been studied in the seminar, the author seems to be concerned mainly with personality, and with a somewhat new and original methodology. There is here a kind of dialectic between basic personality structure and institutions.

The interrelations between personality and culture have been a subject of renewed interest among sociologists in recent years. This mature discussion of the subject should stimulate thought among those working on the firing line of this special field.

Dynamics of Inflammation: An inquiry into the mechanism of infectious processes. By Valy Menkin, M.D. 8°, cloth, 244 pp., with 50 illustrations and 27 tables. New York: Macmillan Company, 1940. \$4.50.

This is a careful and well-documented report of the author's views and experimental work in the field of inflammation, particularly emphasizing the humoral aspects. His extensive researches in the field of leukotaxine and other substances are clearly presented.

After a brief historical survey, sections are devoted to the mechanism of capillary filtration, the capillaries in inflammation, the mechanism of increased capillary permeability, the migration of leukocytes into inflamed tissue, cellular sequence in inflammation, the phagocytic theory, the mechanism of leukocytosis with inflammation, inflammation in relation to immunity, the concept of fixation, the localization of foreign material in areas of inflammation, allergic and anaphylactic inflammation, the role of lymphatics in inflammation and inflammation and bacterial invasiveness in relation to resistance. There is an excellent bibliography.

The author's viewpoint can be summarized briefly as follows: the principal sequences in the development of inflammation are increased passage of fluid through the walls of the capillaries, localization of irritant and migration of the leukocytes.

Cancer: A manual for practitioners. The Committee on Publication: George W. Holmes, M.D., chairman, Shields Warren, M.D., and Ernest M. Daland, M.D. Editor: Channing C. Simmons, M.D. 8°, cloth, 284 pp. Boston: Rumford Press, 1940. \$2.00.

This volume aims to assist the practitioner in the diagnosis of cancer at an early stage, while it is still amenable to treatment—a most commendable purpose. Compiled as part of the program for the control of cancer in Massachusetts, it has been sent to all the practitioners in this state.

The work is comprised of individual essays by men with wide clinical experience and a lively interest in the problems discussed. Most of the authors are Massachusetts men, and it is through their excellent work that the death rate from cancer in this state has finally shown some improvement.

If each practitioner sees only an occasional case of cancer during the year, he needs some work such as this to keep his suspicions of the disease alive. From this standpoint all the facts presented are useful. The only possible criticism is the arrangement of the chapters. It might have helped to develop and sustain the interest of busy practitioners if the first chapters had been practical rather than devoted to the historical and investigative aspects of cancer.

The Foot and Ankle: Their injuries, diseases, deformities and disabilities. By Philip Lewin, M.D. 8°, cloth, 620 pp., with 303 illustrations. Philadelphia: Lea and Febiger, 1940. \$9.00.

This is a very complete and exhaustive review of all conditions concerning the foot and ankle. The illustrations, which are numerous and some of which are from other authors, make the text easy to understand.

The first part of the book takes up in detail the office or ambulatory treatment of various conditions, such as with shoes, supports and plaster casts. Then follow in detail the various operative procedures that are used in this country, with due credit to the originators. Dr. Lewin has kept a very good balance between operative

orthopedics and other conditions, so that this book is of value to practitioners as well as to orthopedic surgeons.

Report on the Sex Question by The Swedish Population Commission. Medical Aspects of Human Fertility Series. Issued by the National Committee on Maternal Health, Incorporated. Stockholm, 1936. Statens Offentliga Utredningar 1936:59. Translated and edited by Virginia Clay Hamilton, M.D. 8°, cloth, 182 pp., with 9 tables. Baltimore: Williams and Wilkins Company, 1940. \$2.00.

Although this book touches on several angles of the sex question, it is mainly an argument for a liberalization of the laws in Sweden concerning the dissemination of birth-control information. It is a scientific treatise devoid of emotional bias. Considerable emphasis is placed on the decline of natality in Sweden, and there is an extensive discussion of probable causes. There is a warning against the intensive use of contraception to a point where it would endanger folk stock. This tendency to such intensive use is recognized by the commission, but the members believe that this would be more than offset if sociologic and economic conditions preventing early marriage were so adjusted as to eliminate this handicap. There is a very sane and dispassionate evaluation of the use of contraception in extramarital relations. There is an excellent chapter entitled "Sex Enlightenment: Its organization in a broadened and improved education for parenthood."

The Doctor and His Patients: The American domestic scene as viewed by the family doctor. By Arthur E. Hertzler, M.D. 8°, cloth, 316 pp. New York: Harper and Brothers, 1940. \$2.75.

Dr. Hertzler's success with his previous volume, *The Horse and Buggy Doctor*, has led him to write a second book, not nearly so satisfactory as the first. To be sure, his object is somewhat different, for he is not telling the story of his life in this volume, but is attempting to analyze the lives of his patients. The comments are, in general, excellent, but there is also considerable uncertain thinking on problems that, although interesting, are not elucidated by the doctor's writing. There is perhaps not much to criticize in this book, but on the other hand, there is little to praise.

A Manual of the Common Contagious Diseases. By Philip Moen Stimson, M.D. Third edition, thoroughly revised. 12°, cloth, 465 pp., with 54 engravings and 6 plates, 4 in color. Philadelphia: Lea and Febiger, 1940. \$4.00.

This reliable, up-to-date, pocket-sized manual is stripped of all nonessentials. The first two chapters deal with the general subject of infection, immunity and serum reactions. The last is concerned with the general management of contagious disease in hospital and home. The rest is devoted to the several specific diseases most commonly encountered in children—diphtheria, Vincent's angina, scarlet fever, measles, rubella, pertussis, mumps, varicella, smallpox, meningococcal meningitis and poliomyelitis. The manual discusses the etiology, pathology, diagnosis, complications, treatment and prevention of each disease. The printing and illustrations are excellent. There is a good index, and a helpful glossary. The book can be highly recommended to the student of medicine or of public health and the practitioner who wants to brush up on the latest accepted opinions in this field.

NUMBER 14

SYMPOSIUM ON DIABETES

THE TREATMENT OF DIABETES WITH DIET AND INSULIN*

ALEXANDER MARBLE, M.D.†

BOSTON

DIET

THE basis of the successful treatment of diabetes is a carefully planned diet adequate in all respects. It is not enough to make provision for the proper amount of carbohydrate, protein, fat and calories; further care is necessary to be sure that an ample supply of vitamins and minerals is included. The best approach to the prescription of any special diet is that of viewing it as a modification of the ideal normal diet so arranged as to promote optimal health. Because the diabetic patient must follow his special diet for years, ample opportunity is afforded for dietary deficiencies to develop, if this possibility is not kept in mind. These can, and must, be avoided by careful planning at the very start of treatment.

Those unaccustomed to the prescription of special diets are often inclined to regard the procedure as complicated. This need not be so. The diabetic diet can be simplified and made easy enough for any patient to understand and follow. The modern diabetic diet allows the average patient fresh fruit, cereal, an egg, one half to one slice of toast, butter and cream for breakfast, and at lunch and supper an average serving of meat, fish, eggs or cheese, liberal amounts of the green, leafy, so-called "5 per cent" vegetables, an average serving of any one of the so-called "10 per cent" vegetables, one half to one slice of bread, perhaps a small potato, butter, and an average serving of fresh fruit. Add to this, tea or coffee, with cream if desired, and at least one half pint of milk for adults and one pint for children, together with a light lunch at bedtime, and one has a simple, easily obtainable, palatable, satisfying diet, furnishing 140 to 160 gm of carbohydrate, 60 to 80 gm of protein,

70 to 100 gm. of fat and 1400 to 1900 calories a day. Naturally modifications of this average diet must be made, depending on the age, sex, weight, activity and complicating conditions of the patient, but if a very few basic food values are learned, substitutions, additions and subtractions may be accomplished easily by doctor or patient.

Although the prescription of the diabetic diet can and should be made simple, this should not be done by the use of blanket forms, since such a practice leads to haphazard and slipshod treatment. Dietary therapy must be individualized. An obese patient requires a diet low in fat and in calories, and a lean one the opposite. Growing children require relatively greater allowances of protein, lime salts and calories than adults do, and the diet must be adjusted so as to provide these. It is possible at times to control the hyperglycemia and glycosuria of a diabetic child and still treat him miserably; and because of adherence to the adult type of diets, which may be relatively lower in protein and calories, growth may not take place and dwarfism may result.

Dietary directions must be stated simply and at the same time specifically. Merely to hand the patient a sheet on which are listed "foods forbidden" and "foods allowed" will usually fail to get the best results, unless the diabetic condition is quite mild and amenable to only slight restriction of diet. A preliminary period of a few weeks in which the patient weighs his food accurately on gram scales provides invaluable training. The inconvenience may be reduced to a minimum by the use of scales with a movable dial, which makes unnecessary the separate weighing of containers. The weighing of food should be regarded chiefly as a means to an end, rather than an end in itself; the object is to train the eye and hand of the patient so that after a few weeks he may pick

*This and the following two papers were presented as a symposium at the annual meeting of the New Hampshire Medical Society, Manchester, May 14, 1940.

†Instructor in medicine, Harvard Medical School, physician, New England Deaconess Hospital.

out with reasonable accuracy the proper portions of food wherever he may be. Occasional return to weighing is desirable to refresh the memory or to become familiar with the amounts of new foods allowable.

It is often said that diabetic diets are expensive because of the necessity for special foods. The truth is that they are only slightly more expensive than average nondiabetic diets, and probably no more costly than nondiabetic diets that are truly well balanced and adequate in all respects. Articles high in carbohydrate, such as bread, potatoes, beans, corn and macaroni, are the cheapest, to be sure, but when they form the basis of a diet, they are apt to make it deficient in certain respects, chiefly in vitamins and minerals. Special foods such as gluten bread, diabetic flour and bran muffins are no longer necessary and represent a needless expense. As a matter of fact, because of its relatively high protein content, gluten bread actually offers little or no advantage over ordinary bread. Almost the only special foods worth considering are the water-packed fruits and vegetables, which permit a varied selection of food at those times of the year when fresh fruit and vegetables may not be available.

All diets should contain enough milk, cream, eggs and cheese to provide an adequate intake of the lime salts—calcium and phosphorus. The daily requirement of calcium is commonly stated to be 0.7 gm. for adults and 1.0 gm. for children. If the calcium requirement is met in the form of foods, the phosphorus intake will almost invariably be adequate also, because of the common association of the two elements. The usual diabetic diet without milk and eggs or their products will often be found to furnish approximately 0.4 gm. calcium a day; approximately 0.1 gm. calcium is contained in 3 eggs and in each of the following: 3 ounces (83 gm.) of milk, $3\frac{1}{2}$ ounces (104 gm.) of 20 per cent cream, 4 ounces (116 gm.) of cottage cheese and $\frac{1}{3}$ ounce (11 gm.) of American cheese.

Whole-grain bread and cereals are far superior to white bread and refined cereals in vitamin and mineral content and should be used in whole or in great part. Patients must be taught to eat green, leafy vegetables and fresh fruit, since these foods contain much in the way of essential minerals and vitamins.

INSULIN

Although everyone can appreciate the natural reluctance of patients to submit to daily hypodermic injections, physicians render better service if they reverse the usual viewpoint and, instead

of advising insulin as a last resort, follow the rule of prescribing insulin in every case, unless a good reason exists for not doing so. A good, general guide is as follows: if, on a diet that is necessary to maintain health, weight and strength, a patient cannot keep sugar free, insulin should unhesitatingly be prescribed in dosage suited to him. Patients must be urged to receive the benefit from as much insulin as they can without developing hypoglycemia or symptoms of overdosage. Almost without exception, every child with diabetes should receive insulin daily from the day of diagnosis.

It helps to assure patients repeatedly that by taking insulin no habit is formed. One must emphasize that the diabetic patient is all the better and none the worse for having taken insulin, and that if, wisely or unwisely, it is later given up, the worst that can happen is that the patient will revert to the condition existing before he began insulin. Actually, many patients with the milder grades of diabetes are able to give up insulin entirely after the condition has been brought under control with energetic treatment.

Whatever is done, patients should not be asked or allowed to take oral preparations in place of insulin. So far, no effective, practicable oral preparation of insulin has been developed. Despite this, patients are all too often allowed or even advised to take these worthless yet expensive products, if one can accept as reliable the statements made by manufacturing concerns of the amount of their products used annually.

The insulin of choice at the present time is the protamine zinc variety. With many patients, one dose of this type of insulin in the morning before breakfast suffices to bring about satisfactory control of the diabetic condition throughout the twenty-four-hour period. However, with children and young adults and in older patients with more severe diabetes, it is necessary to combine with the turbid, slowly acting protamine zinc insulin a dose of rapidly acting, clear insulin taken at the same time in the morning before breakfast. This clear insulin may be of either the so-called "regular" or the crystalline type. Since June, 1939, we have used successfully the crystalline type of insulin almost exclusively in situations in which a rapidly acting variety was indicated. The division of the total dose of insulin between the clear and turbid types has not only the advantage of better control of diabetes but also of preventing night reactions from an overdose of protamine zinc insulin.

When both types of insulin are taken in the morning before breakfast, we prefer to give them by separate injections, administering the clear in-

ulin first. Some clinicians have permitted the mixing of two types in one syringe, thus making necessary only one puncture of the skin. This has two disadvantages. In the first place, manufacturers place in protamine zinc insulin an excess of protamine; when regular or crystalline insulin is mixed with protamine zinc insulin, a part of the clear type is bound by the protamine so that, depending on the duration of contact between the two types, to a greater or less and probably to a variable degree, one has a slightly larger dose of protamine zinc and a slightly smaller dose of clear insulin than one planned at the outset. Of even more importance is the fact that it is technically difficult to withdraw into one syringe accurately a dose of two types of insulin from two different vials. On the basis of careful studies of the blood-sugar response, Wauchop¹ has likewise concluded that better results are obtained if the two types of insulin are given by separate injections.

When the two kinds of insulin are taken daily in the morning before breakfast, the adjustment of the insulin dosage becomes very simple. Two tests of urine for sugar are important: the test of urine voided before breakfast (preferably not an overnight specimen but a second specimen passed a few minutes later but still before insulin and breakfast), which indicates the effect of the protamine zinc insulin taken the day before; the test of urine voided just before the noon meal, which indicates the effect of the crystalline insulin taken on the same day. With the average patient, these two tests, if carried out by Benedict's method, should give reactions varying between a blue and a light green. Increases or decreases of two units at a time may be made in either or both types of insulin as the urine tests dictate. It is usually best to allow two or three days between changes.

There are certain misconceptions prevalent regarding the use of insulin. Among these may be mentioned the fear of using insulin in the presence of coronary heart disease. In such patients, insulin should be used without hesitation to control the diabetic condition, although with sufficient caution and care to avoid hypoglycemic reactions. A second error is the very prevalent assumption that during times of acute illness, insulin should be omitted when the patient is not eating. This single point has caused untold difficulty for diabetic patients. Repeatedly, patients have been admitted to the hospital in diabetic coma that has resulted from the omission of insulin during an acute infection accompanied by gastrointestinal symptoms, which prevented eating the usual amount of food. Patients forget that, particularly if the diabetic condition is severe, a certain amount of

insulin is necessary daily, even though no food is eaten; this becomes all the more important if an infection with fever is present. The patient must be instructed over and over again never to omit insulin during an acute illness, unless the urine is found at three or four hourly intervals to be free from sugar. A third erroneous belief is that in certain patients "insulin does not work." In reporting deaths of diabetic patients, statements are sometimes made that insulin was entirely ineffective in lowering the blood sugar, despite the giving of large amounts, at times several hundred units, within a few hours. The fact is that in certain conditions, particularly acidosis, coma and those rare cases of so-called "insulin resistance," the relative effectiveness of a unit of insulin drops markedly, so that one must discard the usual rules of action and give larger and larger amounts until the desired effect on the blood sugar is obtained. This may mean, as in certain of our patients, approximately 2000 units a day for as long as ten days, but it has been our experience that insulin can never be said to be ineffective, provided large amounts are given early enough.

It has recently been stated that if a diabetic patient is given protamine zinc insulin daily and is kept free from symptoms characteristic of the disease, and if the urine is kept free from acetone bodies, glycosuria and hyperglycemia may be disregarded, even though they may be marked.² We enthusiastically approve of the use of protamine zinc insulin, but we believe firmly that it should be used in such dosage, with or without an appropriate dose of crystalline insulin and a restricted diet, that glycosuria is completely or nearly abolished, and the blood sugar kept at a level not far above normal. We believe in the early, vigorous treatment of diabetes and the careful, continuous control of the condition in an attempt to restore normal conditions in the body so far as possible; this conviction has been strengthened by the results of studies in animals reported recently by Haist, Campbell and Best³ and by Lukens and Dohan.⁴ We believe that anyone who follows his patients over years of time until death, and who compares the results in those treated poorly and those treated well, will come to the conclusion that the careful treatment of diabetes pays. Patients may appear to be well for months and years despite constant glycosuria and hyperglycemia, but our experience leads us to believe that these abnormal conditions in the end prove harmful to the patient. Try as we may, it is usually impossible to achieve ideal control of the diabetic condition, but that should be the aim of treatment in every case.

Less than 100 per cent control is a situation to be tolerated rather than to be sought. With such care, one may reasonably hope that most diabetic patients may happily and usefully live out a life expectancy approaching closely that of the normal person, meanwhile avoiding complications characteristic of the disease.

DIABETES IN YOUTH*

PRISCILLA WHITE, M.D.†

BOSTON

DURING the last few years, clinical, genetic and physiologic research has done much to clarify and change our concept of diabetes, and this discussion is an attempt to correlate this newer knowledge with the cause, prevention and treatment of diabetes and its complications in childhood, and the cause, prevention and treatment of the common accidents occurring when diabetes complicates pregnancy.

The management of diabetes in the young patient arouses general interest, in spite of the fact that the incidence is certainly not more than 1 in 2500 children under fifteen years of age; however, the complications are sufficiently manifold to bring these patients into all branches of medical and surgical practice.

A brief discussion of the fundamental cause and its mechanism of action is of value, because these are the bases on which serious attempts at alleviation of both experimental and clinical diabetes are being made.

That the tendency to develop diabetes is inherited cannot be doubted. It is the one link connecting all age groups. In childhood, when the expanse of life permits it, family histories of the disease increase with duration. Only 20 per cent of children in our clinic have a known diabetic relative when first seen, but after they have been followed for fifteen years 50 per cent have a known heredity.

The actual evidence in favor of the theory of inheritance of the diabetic tendency lies in the demonstration of diabetes in similar twins, the statistically significant excess of diabetic incidence in the close blood relatives of diabetic as compared with those of nondiabetic patients, and the demonstration of Mendelian ratios of the recessive type in a large series of cases selected at random and in presumably latent diabetic patients.

Diabetes, even in the child, is not evident at birth or soon thereafter but appears to follow a rhythmic age behavior stimulated at pubescence and at senescence. Of recent years its occurrence has been attributed to complex endocrinal factors — especially an interrelation of the pituitary gland and the pancreas.

At the onset of the disease the child presents presumptive evidence of hyperactivity of the pituitary gland: his height, metabolism and bone and dental development are in advance of the normal for his chronological age, and his puberty is precipitated.

The final production of diabetes by injection of anterior pituitary extract has led to attempts at alleviation by pituitary inhibition. Radiation and extirpation are obviously too dangerous. Estrogens and androgens theoretically capable of depressing pituitary activity have been tried, the former with some success.¹

Low-carbohydrate diets and hyperinsulinization of the patient at onset have also been attempted, the former in our clinic prior to the discovery of insulin and up to the last decade. Hyperinsulinization was seriously attempted in childhood diabetes in 1930, by Brush² in New York City, and for the same purpose perfect control of diabetes is being attempted by Jackson, Boyd and Smith³ today. Cures have not been reported from any of the attempts. The latent rather than the out-and-out diabetic person must be sought for these experiments, but control of the spread of the disease may be sought by out-breeding, that is, by advising against the intermarriage of families with diabetes.

The treatment of diabetes in children consists in regulation of diet, administration of insulin, adjustment of exercise, education of the entire family and protection of the child against himself.

The caloric requirement, though dependent on surface area, follows age closely in childhood. For simplicity we prescribe calories by age: 1000 at

*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 14, 1940.

†Instructor in pediatrics, Tufts College Medical School; physician, New England Deaconess Hospital.

age one and 100 per year of age until the completion of growth and development. Carbohydrate, protein and fat are prescribed in gram ratios of 2.1 1 respectively.

Insulin is administered to all diabetic children, preferably continuously from the day of recognition of the disease. Few children, only 10 per cent, do well with protamine zinc insulin alone, and 90 per cent require both the rapidly and slowly acting types. The initial prescription for a newly contracted case, which for the time being will do well with protamine zinc insulin alone, is based on age—under five, 10 units, between five and ten, 20 units, and between ten and fifteen, 30 units. The readjustment of the long standing case is facilitated by continuing with the usual dose of rapidly acting insulin before breakfast, and supplementing with twice that quantity of protamine zinc insulin. Readjustments are then made in accordance with premeal and retiring specimens of urine.

The chemical standards for control are glycosuria of less than 10 per cent of the carbohydrate intake, a normal blood-sugar level before meals and a blood-cholesterol level below 230 mg per 100 cc.

Postmeal exercise and premeal rest periods are advocated. To the parents one must emphasize the fact that diabetes is not a bed or chair disease but an exercise disease. Education of the entire family, equal to that which is rapidly acquired by the child, cannot be overemphasized. The acceptance of a child's statement relative to diabetic facts as a substitute for more accurate knowledge that has been acquired by the family through self-education leads to tragedy for the child and unsatisfactory care of the diabetes. To provide constructive protection against the child's feeling of security in spite of indiscretions, it has been necessary to start educational units in camps and schools.

Controllable and seemingly uncontrollable complications occur during the course of diabetes in the young patient. Coma, infections, hepatomegaly, some of the skin complications and failures of growth and development are now correctable. The degenerative and deficiency diseases remain unsolved, but, I believe, are not unsolvable. These complications I shall merely catalog, and thus summarize their essential differences in behavior and their management when they occur in childhood rather than in adult life.

Excess of incidence, simplicity of treatment and sureness of favorable prognosis characterize coma in the young population. The severity of the disease in the child, as well as the occurrence of irregularities of diet, the omission of insulin and infections, account for the relatively high inci-

dence. The treatment consists largely of three measures—insulin, fluids and gastric lavage. The prognosis for recovery, unless the patient has a lethal infection or is actually moribund before treatment is inaugurated, is 100 per cent.

The decreased incidence of tuberculosis in the entire population is reflected in the juvenile diabetic population. Chemotherapy protects the adolescents from deaths from septicemia, which formerly so often followed infections of the skin and urinary tract.

Hepatomegaly, of interest physiologically and of importance clinically because of the bouts of abdominal pain, is corrected and prevented by protamine zinc insulin. One biopsied case in our series showed 10 per cent fat and 12 per cent glycogen in the liver.

Metabolic skin lesions are seen frequently in the child. Xanthosis, due to the excessive intake and failure of metabolism of carotene, is corrected when the foods high in carotene are eliminated. The lesions of xanthoma diabeticorum, which we have not seen in a patient treated with protamine zinc insulin, disappear when the blood fat falls to normal levels. The early lesions of necrobiosis lipoidica diabeticorum—perhaps cutaneous gangrene—have been controlled by x ray therapy, but no satisfactory treatment of the late lesions has been found.

Neuritis seldom occurs in childhood, but is not uncommon in patients in their twenties. It has not been controlled with vitamin B therapy. Diabetic nocturnal diarrhea, commoner in the young patient and frequently an accompaniment of neuritis, appears to have been controlled by liver extract.

The incidence of degenerative complications in juvenile diabetes far exceeds expectation. Cataracts occur early in its course, are not always progressive, and can be treated surgically. Retinal hemorrhages may be reversible. Retinitis may also be reversible but, unfortunately, the incidence of its severest form—retinitis proliferans—is high in long standing severe diabetes.

Based on an analysis of diabetic children who have had the disease for fifteen years, arteriosclerosis appears inevitable. The lesion can be attacked from different angles. If it results from uncontrolled diabetes, hyperglycemia, acidosis or dehydration, the more perfect control of the diabetes by combined insulin therapy should prevent it in the future. If it is due to improper metabolism of fat, lipotropic substances, such as choline and lipocain, may prevent its occurrence. Even though it may prove to be a degenerative stigma inherited with diabetes, arteriosclerosis should yield to some therapeutic agent, just as

diabetes is controlled by insulin. If, as seems possible, it is a part of the complex endocrine imbalance, more perfect and combined endocrine therapy may solve the difficulty as it appears to have done in the next two problems, namely, failures of growth and development, and accidents of pregnancy in diabetes.

The situation of pseudodwarfism in diabetes appears paradoxical. The failure of growth is not observed until several years after onset. Obesity occurs in proportion to the duration of retarded growth, and the child has the characteristics of pituitary failure—delayed development of bone and of teeth, with normal intelligence. Three possible explanations are that it is a congenital anomaly, the result of undernutrition or the result of fatigue of the pituitary gland. Along with failure of growth, mildness of diabetes usually occurs. These patients respond to intramuscular anterior pituitary extract and oral thyroid therapy. The increased severity of the diabetes is sacrificed for the social and economic importance of the problem.

A mechanism similar to that responsible for the production of diabetic pseudodwarfism appears to explain the high incidence of accidents when pregnancy complicates diabetes. These data are more convincing because, although we have not measured the hormones in the dwarfish patients, we have measured the hormones of our pregnant diabetic women.

Our present conception of the mechanism of the accidents in diabetic pregnancies has been the outcome, first, of the realization that insulin therapy did not lower fetal mortality (preinsulin 42 and insulin 38 per cent) and, secondly, of the behavior of diabetic pregnancies in relation to the pregnancy hormones, which Smith and Smith⁴ first studied in a number of our patients, to extend their work on pre-eclamptic toxemia.

Our present conception is that an abnormal rise of serum chorionic gonadotropin after the twentieth week predicts accidents, that the accidents are caused by failure of production or metabolism of estrin and progesterin, and that they are prevented by continuous substitutional estrin and progesterin therapy in replacement doses.

This statement is based on a series of 84 cases of completed pregnancies studied between 1936 and 1941. The early analyses were made by Smith and Smith as part of their research, the later ones in the laboratory of the New England Deaconess Hospital, where we have attempted to establish them on a routine rather than a research basis.

Classified by prolan values, the rise occurring two to six weeks before clinical signs, there were

36 patients with normal behavior. There was no toxemia, no premature deliveries, and three neonatal deaths,—due to asphyxia pallida, hemorrhagic disease of the newborn and multiple congenital anomalies,—making fetal survival 92 per cent.

Twelve patients with significant rises had no treatment. All the mothers had an abnormal course, 9 of the 12 had pre-eclamptic toxemia, 3 had premature deliveries, and fetal survival was 42 per cent. The clinical picture was clarified. Maternal and fetal behavior fell into two classes. Either the mother developed a lightninglike toxemia, usually with hydramnios, and delivered a macerated stillborn child, or without toxemia she delivered prematurely a large atelectatic infant dying within a few hours of birth.

The next step was an attempt at prevention. At the suggestion of Smith and Smith, estrin and progesterin* in doses as near replacement as possible were given continuously after the rise of the prolan. Signs of toxemia were controlled. Premature deliveries did not occur, and fetal survival was 13 out of 14 cases, or 93 per cent, contrasted with 42 per cent in the untreated group.

Although this therapy appeared to be successful, because of the cost it was a physiologic curiosity. For this reason, at the New England Deaconess Hospital we substituted synthetic and inexpensive preparations, Stilboestrol† and Pranone. Eleven cases were treated with oral substitutes. There were two fetal deaths, including one due to erythroblastosis. Another 11 abnormal cases were treated with intramuscular Stilboestrol and Proluton. Ten of these infants survived. The fetal survivals in the three groups are as follows: normal prolan, 93 per cent; high prolan, untreated, 42 per cent; and high prolan, treated, 89 per cent.

The characteristics that occur in the infant are gigantism and hyperplasia of the islands of Langerhans, which we correlate with the imbalance of pregnancy hormones. In the experimental animals prolan has also produced both these conditions.

Congenital anomalies, usually not fatal, are a manifestation of the hereditary nature of diabetes. Diabetic patients themselves have similar anomalies. Hypoglycemia, not a fatal accident, occurs in most newborn infants.

* * *

Thus the outlook for diabetes in the young patient today is good. Duration of life is assured. Progress in prevention and control of complications is advancing. In two periods of life the diabetic patient, like the experimental diabetic animal, shows definite evidence of hormonal in-

*Progynon and Proluton were partly supplied through the courtesy of the Seehring Corporation, Bloomfield, New Jersey.

correlation. In the animal this relation appears most marked among the pituitary gland, pancreas and adrenal glands, but in the clinical diabetic patient, when growth and development and pregnancy complicate the disease, an interrelation of gonads, pancreas and pituitary glands is most marked.

DIABETIC HAZARDS*

ELLIOTT P. JOSLIN, M.D.†

BOSTON

PERSONS with sugar in their urines run many hazards. The first is that of being diagnosed a diabetic when the disease is nonexistent. Approximately one seventh of all the patients we have seen with sugar in the urine were thought by us not to have had diabetes at the first visit. One must not be careless with this group. Such patients should have their urines examined every three months for life, warned against overweight and cautioned to report to their physicians if any unusual symptoms occur. In the early days, when blood-sugar tests were not available, 10 per cent of these cases developed diabetes, but more recently the percentage has dropped to 6; it is barely possible that with the more accurate interpretation of glucose-tolerance tests the number of persons who from the experience of the past would later develop diabetes will be still further curtailed, because they will be proved to have had the disease originally.

The glucose-tolerance test itself is a hazard if the patient's diet has previously been restricted in carbohydrate. Such patients, whether or not they have ever shown sugar in the urine, may give a positive reaction to the test. I need not amplify this statement, but simply re-emphasize the necessity of learning from the patients whether they actually have been restricting their carbohydrate before putting them through this procedure. One such case occurred some months ago. A patient with glycosuria came for diagnosis. Sugar was found in the urine, and he was given a glucose-tolerance test. It indicated that he had diabetes, because the blood-sugar level rose above 170 mg. per 100 cc. during the test, and glucose was present in the specimens obtained. Knowing that his diet had been restricted, I advised him to live on a free diet during the continuance of his vacation

and to return in ten days. This he did. A repetition of the test showed the urine to be perfectly normal.

Another diagnostic hazard is the failure to discriminate between pentose or fructose and glucose. We have had 9 such cases. One of these, a child four and a half years of age, had been given insulin for two years. When he arrived for treatment, despite his trip of 1000 miles, the blood sugar was normal. It continued normal for a day or two despite a slight upper respiratory infection. It is true that sugar was present in the urine. However, the technicians followed the established rule that whenever a new patient comes for treatment, pentose must be excluded if the Benedict test is positive. This is very simply done. One performs the Benedict test in the ordinary way, but sets up a duplicate without heat and keeps the mixture of urine and Benedict's solution at room temperature until the following morning. If pentose is present, the Benedict's solution will be reduced even without heat, but of course this will not take place with glucose. Such a reduction of Benedict's solution in the cold also occurs with levulose. You can imagine, therefore, my gratification in being able to tell the parents of the child that diabetes did not exist and that a special diet and insulin were unnecessary. All our cases, and apparently all such cases thus far recorded have occurred in Jews; the origin of those traced by Lasker¹ has been in what was formerly Poland.

An identification card should be in the pocket of every diabetic patient. It is true that with protamine zinc insulin, reactions are less common than heretofore, but they may occur and the patients must not take any chances. On the reverse side of the identification card that we give our patients are rules for the differential diagnosis of an insulin reaction and diabetic coma. To drive home the desirability of an identification card, I was told of a patient far away from New England who was

*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 14, 1940

†Medical director, George F. Baker Clinic, New England Deaconess Hospital.

put in jail; the disease was unrecognized, and death followed. A happier, although somewhat embarrassing result occurred with one of my diabetic clergymen. He was candidating for a church in a new locality, but when he reached the town, woke up to find that he was in jail instead of in the pulpit. Perhaps his life was saved by an identification card or the mute witness of a couple of lumps of sugar in his pocket.

Living alone is truly a diabetic hazard. Each patient should have a close friend. A diabetic patient who has a diabetic twin is fortunate. My diabetic girls are so bright that they sometimes marry doctors, and my diabetic boys so intelligent that they deplete the ranks of the nurses at the New England Deaconess Hospital. Perhaps I should not say so much about the danger of living alone, but I have known of such a method of life resulting in dire catastrophes.

Diabetes should be acknowledged by those who have it. It is not a disease to be ashamed of unless one has been informed that he or she is hereditarily disposed and yet has become fat. One in four of all the people in the country has a diabetic relative. A good share of those who have diabetes could not have prevented it, even if they had avoided obesity, because they were born with a diabetic heredity. If the presence of diabetes is more generally admitted by intelligent patients, people will become more and more accustomed to it and will assume, just as they properly should, that diabetic patients can get along very well and be of service to themselves and others. Meanwhile their friends will allow them to be protected. Diabetic patients often undergo social embarrassments needlessly. Thus they may have taken their insulin, but the expected meal thereafter may be delayed, and a reaction may ensue. Although this is less frequent with protamine zinc insulin than formerly when, with regular or crystalline insulin, injections were made several times a day, reactions do occur. The diabetic woman may be very energetic in preparing the food at a church strawberry festival, and so busy that she forgets the lengthening interval that has occurred between the dose of insulin and the beginning of the meal; a reaction may take place, to the confusion of all concerned. If the disease had been less concealed, the hostess or a friend might have shared in preventing the delay in eating.

Unusual exercise promotes the tendency to a reaction. With regular insulin or crystalline insulin one takes a little extra carbohydrate at the first sign of a reaction, but patients employing protamine zinc insulin will do better if they eat their

extra quota of carbohydrate at the beginning of the exercise.

Gastrointestinal upsets often are the precursors of a reaction. During such episodes, patients should always take some carbohydrate at frequent intervals, electing the form that can be best retained—tea or coffee with sugar, milk and Vichy water, ginger ale or similar preparations.

Automobile driving is a definite hazard. The patient should make it a rule never to drive an automobile unless carbohydrate has been taken within two hours. Of course it is safer for him to have a companion in the car, and that is another reason for not living alone. On the other hand, I wish to state emphatically that I have known diabetic patients who made a practice of driving thousands of miles a year in their daily work and yet never got into trouble. These persons, however, are most reliable. I confess that at one time I knew of a diabetic woman who drove a school bus. It always worried me, but I never had a more reliable patient. She never drove without taking food a very short time before driving, and now that she has given up driving on account of age I can say that she never had an accident; in fact, once when there was an emergency on account of trouble with the automobile, she mastered it. One of my very best patients has been an aviator, but fortunately he is now married and has given up acting as a pilot.

The differential diagnosis of diabetic coma and an insulin reaction is often difficult. I cannot blame the doctor who does not have an opportunity to see many diabetic patients if he fails in such a diagnosis. That is why we ask all our patients to carry an identification card with the points in diagnosis on the reverse side. I have known tragic examples of failure in such a diagnosis. Aside from the standard points of differential diagnosis, what should be done? Recourse must be had to a laboratory.

Laboratories are lifesaving in diabetes because through them the doctor can intelligently treat a patient with an insulin reaction or diabetic coma. Each doctor and each patient should always know where blood-sugar tests and tests for acidosis, including the carbon dioxide content or combining power of the blood plasma, can be performed promptly, not only by day but by night, on Sundays and on holidays. Laboratories cost only about \$200. No town should be without a laboratory in which a blood-sugar test can be done. Doctors must co-operate more and more to make this possible. In one town in Maine there is a diabetic child whose doctor taught the young nurse attendant how to do a blood-sugar test. She has done

tests for years, once a week, for the child. She does tests for the patients of other doctors, and when a case of diabetic coma came to the fourteen-bed hospital in the town, she was the one called on to clinch the diagnosis by estimating the sugar in the blood. I hope that some of my diabetic girls can be trained to be technicians, because then they will demonstrate their usefulness to the communities in which they live.

The omission of the routine test of the urine is dangerous in diabetes. I always dread to have a patient give up testing because for a time he has found his urine constantly sugar free. Of course some patients can rightly do this. The ordinary patient, however, should test the urine daily. Over and over again the rule has been relaxed only to find later that the diet has also been relaxed. Thousands of useless tests are better than the failure to recognize the return of active diabetes with or even without the development of diabetic coma.

A double diagnosis should always be considered in diabetes. A single diagnosis to explain all the symptoms that a patient manifests was the rule we were all taught to adopt in our early medical education. Such a rule, however, is fallacious in diabetes, and double diagnoses are now more frequent. I took off my hat to a young physician, who came to work with us after graduating from the Peter Bent Brigham Hospital, when he diagnosed cerebrospinal meningitis in the presence of an attack of diabetic coma and with prompt, intelligently applied and efficient treatment saved the patient's life. Over and over again this rule holds in diabetic coma. The patient in diabetic coma seldom dies, unless there is an additional diagnosis such as appendicitis, cholelithiasis, pyelitis, paraneurphic, ischiorectal or vulval abscess, coronary thrombosis, uremia, apoplexy or pneumonia. It is safe to assume, when a diabetic patient is not doing well, if his diet is adjusted and if he is taking the usual dose of insulin, that another diagnosis exists; one should always look for the accompanying diagnosis.

Errors in measuring insulin are common. Regardless of whether the patient is a doctor, lawyer or a minister, whether he is a patient who has taken insulin for a week or for ten years, it is possible for such errors to occur. Therefore, it is a good rule always to ask to see the syringe that the patient uses, to check up closely both the type of insulin and how he measures and injects it and never to trust to his story if in any way the diabetes is not being properly controlled when one thinks that it should yield to treatment. To guard against errors in measuring insulin, our group believes that the simplest type syringe, namely, a 1-cc. syringe divided into tenths, is the best. I

considered myself fortunate to be able to tell a doctor, who was health officer of a large city, that his uncomfortable feelings during the latter part of the morning were not due to his circulation, but to the fact that he was taking 60 units of insulin when he thought he was taking 30 units.

Insulin should never be omitted when sugar is present in the urine. The mere fact that a patient is not eating is no reason to omit a dose of insulin. Omit insulin only when the urine is sugar free. Of course, one always checks up the statement that sugar is or is not present in the urine. It may have been secreted from the kidney into the bladder at 2 a.m. and consequently found in the urine when the bladder is emptied at 7 a.m., thus giving rise to the patient's wrong impression that the urine secreted at that particular moment shows sugar. A second specimen test a few minutes later will clear up the situation, provided that the bladder has been thoroughly emptied at the previous voiding. Any patient who improves so much that he can be told that insulin can be omitted must be doubly cautioned to test his urine more frequently in the future than ever before to be sure that the sugar does not return. Unless the doctor does this, he is likely to be embarrassed at a future visit of the patient or by an emergency summons.

Failure to recognize that diabetes can improve and grow milder is a definite hazard. It is almost as serious as failure to recognize that it can grow worse. In one case the failure may lead to an insulin reaction, and in the other to diabetic coma. There are so many mild diabetic patients today who do improve, and such a considerable percentage who by living faithful dietetic lives and taking proper exercise could give up their insulin safely, that it is a shame not to recognize their improvement and enable them to do so.

Toes are a greater hazard than teeth. A diabetic patient can have a toothache, and he will fly to the dentist to have it treated or taken out. But if he has a toe ache, most likely he will neglect it or eventually go to the doctor, who may dress it instead of taking it off. If these patients could only get rid of their toes as easily as they get rid of their teeth, how fortunate they would be. Other lesions of the feet arise in diabetes, resulting in gangrene, but most of the troubles in the feet begin in the toes. Never let a diabetic patient go through a visit in your office unless he takes off his shoes and stockings. This is sometimes a sad and disagreeable procedure for the doctor, but if the feet are always examined, they will be cleaner and cleaner at each subsequent visit, and the time may come when you will be able to trust the removal of one instead of two stockings, although that is a very

risky procedure. I do not dare to look up how much of the free-bed money for diabetic patients in the New England Deaconess Hospital is spent on neglected toes, but I venture to say that the charity money devoted to the toes of elderly patients is five times that expended on diabetic patients in their teens. Consider the difference in the efficiency and expectation of life of the two groups.

A defeatist policy will never win a diabetic war. Always attack diabetes aggressively—the more aggression, the younger the diabetic and the more recent the onset of the disease. Best² has shown that diabetes can be prevented in a dog following the injection of anterior pituitary extract, provided insulin is simultaneously administered. Indeed, if a dog is fasting it is impossible to give it diabetes by the injection of anterior pituitary extract. Lukens³ has shown in a cat that even after two months the diabetes definitely produced by injections of anterior pituitary extract can be

cured by energetic treatment with insulin. In the cat, for some months following the development of the disease, the islands of Langerhans in the pancreas are in the stage of hydropic degeneration, and in that stage the lesions are reversible and the diabetes can be cured.

How thankful I am that the words "prevention" and "cure" have now entered the vocabulary associated with diabetes, even though they apply alone to experimental diabetes in an animal. There is no question in my mind that some of those who hear me today will live to see the extension of these experiments to diabetes in man.

THE TREATMENT OF PNEUMOCOCCAL PNEUMONIA*

With Special Reference to the Use of Sulfathiazole, Intramuscular Serum, the Francis Test and Histaminase

CHARLES A. JANEWAY, M.D.,† AND PAUL B. BEESON, M.D.‡

BOSTON

THE specific therapy of pneumococcal infections has been undergoing changes so rapidly in recent years that careful evaluation of the various types of therapy has been impossible, with the result that there are many uncertainties and differences of opinion concerning relative merits. It is the purpose of the present communication to report experiences with 80 cases of pneumococcal pneumonia that were treated at the Peter Bent Brigham Hospital between October, 1939, and June, 1940.

Detailed statistical analysis of a series of cases of this size is not worth while. The type incidence was not unusual; all but a single case fell into one of the 32 pneumococcal types of Cooper. The average age of our patients, forty-nine years, is considerably above that usually reported. Bacteremia was found in only 10 cases. The gross mortality rate in a small series of cases is not of much significance, since it depends considerably on chance. With the extremely effective agents now available, mortality is rare in ade-

quately treated cases unless the pneumonia is complicated by some other serious debilitating condition, such as heart disease, cancer or chronic alcoholism, or is far advanced when therapy is begun. A brief survey of the 9 fatalities in the present series bears this out.

CASE REPORTS

CASE 1. G. B. (No. 57025), a 70-year-old man, was admitted after several days' illness—the exact duration was uncertain. The blood culture contained many Type 9 pneumococci, estimated at 60,000 per cubic centimeter. The leukocyte count was 5200. Three lobes were involved. The patient was treated with sulfathiazole, concentrated rabbit serum intravenously and blood transfusions (1200 cc.). He died 36 hours after admission. Blood culture just before death showed less than 1 colony per cubic centimeter. Autopsy showed dense consolidation of three lobes, massive empyema, and purulent arthritis of one sternoclavicular joint.

CASE 2. M. D. (No. 57187), a 60-year-old woman and a chronic alcoholic, was admitted in coma, with multiple bruises and a fractured clavicle, following a fall during a drinking spree. The patient was unconscious for 30 hours. On the 4th hospital day, signs of pneumonia (Type 8) developed in two lobes; the patient succumbed 40 hours later. She was treated with sulfathiazole, and concentrated horse serum intramuscularly. Autopsy was not permitted.

*From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Medicine and Department of Bacteriology and Immunology, Harvard Medical School.

†Instructor in medicine and in bacteriology and immunology, Harvard Medical School; associate in medicine, Peter Bent Brigham Hospital.

‡Instructor in medicine, Harvard Medical School; formerly, resident physician, Peter Bent Brigham Hospital.

CASE 3. A. W. (No. 562399), was a 51-year-old woman. Since childhood she had had rheumatic heart disease involving the mitral and aortic valves, and had been decompensated previously. Operation, consisting of closure of colostomy following resection of colon for regional ileitis, was performed. The patient developed signs of pneumonia (Type 14) in two lobes on the first postoperative day, and was treated with sulfapyridine and with concentrated rabbit serum intravenously. The response was excellent; the temperature fell to normal and the signs of pneumonia cleared rapidly. On the 8th postoperative day, the patient went into collapse and died rather suddenly. Autopsy showed that the pneumonia was practically gone, but there was a large fresh mycotic aneurysm on a mitral-valve leaflet.

CASE 4. J. F. (No. 57224), a 68-year-old man with a Type 8 infection, was admitted and gave a history of failing health, with insidious onset of respiratory infection followed by pneumonia during two weeks previous to entry. He was found to have lymphatic leukemia, with generalized lymph-node enlargement and splenomegaly; the leukocyte count was 400,000 to 600,000. There were signs of pneumonia in two lobes. The patient was treated with sulfapyridine and concentrated horse serum intramuscularly. There was no response to treatment. The condition steadily became worse, and the patient died on the 7th hospital day, having been stuporous for 3 days. Permission for an autopsy was not obtained.

CASE 5. P. D. (No. 56391), a 45-year-old man with a Type 5 infection, had been followed in the outpatient clinic for many years because of chronic cough, dyspnea and asthma. Previous x-ray and physical examinations had shown marked enlargement of the right side of the heart—cor pulmonale. The patient was admitted to the hospital, gravely ill, on the 4th day of pneumonia and showed extreme cyanosis and dyspnea. He was treated with oxygen and sulfapyridine. He died 5 hours after admission. No autopsy was performed.

CASE 6. C. M. (No. 57214), a 67-year-old man with a Type 3 infection, was admitted on the 6th day of pneumonia. Blood culture on admission contained 50 colonies of Type 3 pneumococci per cubic centimeter. The leukocyte count was 4200. Three lobes were involved. Chest aspiration yielded a small quantity of pus, either from empyema or from a lung abscess. The patient was treated with sulfathiazole, sulfapyridine and concentrated rabbit serum intravenously. He died on the 2nd hospital day. No autopsy was performed.

CASE 7. J. H. (No. 56503), a 73-year-old woman with a Type 3 infection, was admitted on the 7th day of disease; two lobes were involved. There was an old history of hypertension. The patient was treated with sulfathiazole and concentrated rabbit serum intravenously, with no response other than a fall in temperature, and died 55 hours after admission. No autopsy was performed.

CASE 8. C. D. (No. 56309), a 73-year-old man with a Type 4 infection, was admitted with a history of poor health for several weeks; he had been vomiting for 2 or 3 days before admission. He was extremely dehydrated. Examination revealed consolidation of the entire right lung. The patient was treated with sulfapyridine for several days, with no obvious effect on the pulmonary disease. The temperature remained normal throughout his stay in the hospital. On the 14th day his pulse suddenly became rapid and weak, and he died within a few hours. Autopsy

showed an unresolved pneumonia in the right lung, estimated by the pathologist to be of at least 6 weeks' duration. Death probably was due to recent perforation of a gastric ulcer. Incidental findings were carcinoma in the cecum and in the prostate.

CASE 9. G. L. (No. 56837), a 45-year-old man with a Type 3 infection, was admitted on the 5th day of pneumonia with a history of chronic alcoholism. Two lobes were consolidated. The leukocyte count was 1200. The blood culture was positive—50 colonies per cubic centimeter. The patient was treated with sulfapyridine. He showed evidence of peripheral vascular collapse on admission, and died within less than 24 hours. Autopsy showed lobar pneumonia (right middle lobe), bronchopneumonia (left upper lobe), atelectasis of the rest of the lungs, bilateral hydrothorax, fibrinous pericarditis, cholelithiasis and hepatomegaly.

The chemotherapeutic agents used in these cases were sulfapyridine and sulfathiazole.* The anti-pneumococcus serums were chiefly those supplied by the Commonwealth of Massachusetts (concentrated horse serum for Types 1, 2, 5, 7 and 8 and commercial concentrated rabbit serum for Types 4, 9, 14 and 18). Commercial rabbit serums of other types were also available for seriously ill patients. Two patients were treated with a Type 3 concentrated rabbit serum.†

The general plan of treatment was to administer either sulfapyridine or sulfathiazole to all patients, and in addition to give serum to all patients with types of pneumonia for which serum was available. This routine use of serum is at variance with the practice of some authorities,^{1,2} who advocate treatment with drugs alone, resorting to serum only in certain types of cases, such as those not responding to the drug in twenty-four to thirty-six hours and those with bacteremia, renal calculi and so forth. Our reasons for employing serum routinely in addition to the sulfonamides were as follows: there is good evidence, both experimental and clinical, that a combination of chemotherapy and antiserum is more effective against pneumococcal infections than is therapy with either one alone; by giving serum in addition to sulfapyridine, the dosage of the drug can be reduced considerably; it is reasonable to suppose that the less drug that has to be given, the less danger of toxicity; also patients who are not receiving sulfonamides eat better and have a more rapid convalescence.

In these cases the average total dose of sulfapyridine when used alone was 17.8 gm., as compared with 10.2 in patients treated also with serum. For sulfathiazole the respective averages were: 31.2 and 16.7 gm. When both chemotherapy and

*The sulfathiazole and sodium sulfathiazole were supplied through the courtesy of the Squibb Institute for Medical Research, New York City.

†Supplied through the courtesy of the Squibb Institute for Medical Research, New York City.

serotherapy were employed, the plan generally followed was to give sulfapyridine or sulfathiazole as soon as the diagnosis of pneumonia was made. After six to twelve hours of drug therapy, treatment with serum was instituted. The reason for this spacing of therapy was to allow time for absorption of the drug and the attainment of a therapeutic blood level, and to allow for the lag period that probably exists before the bacteriostatic effect of the sulfonamide compound begins to take effect.^{3,4} Then an attempt was made to bring about a critical termination of the infection with serum. As soon as this occurred, all therapy—drug and serum—was stopped. Thus in many cases no therapy was given after the first ten or twelve hours, as is shown by the following typical case.

CASE 10. L. K. (No. 56546), a 51-year-old man with a pneumococcal infection Type 3 and a negative blood culture, was admitted on the second day with involvement of the right upper lobe. Sulfathiazole was begun two hours after admission. A Francis test was negative. Concentrated rabbit serum (150,000 units) was given intravenously 8 hours after admission. Three hours later the Francis test was still negative, and therefore 50,000 units of serum was administered intravenously. Two hours later the Francis test was strongly positive. All therapy was stopped, and the pulse fell from 150 to 95, followed by a more gradual drop in temperature. The total dosage of sulfathiazole was 10 gm. The convalescence was rapid and uneventful.

COMPARISON OF RESULTS WITH SULFAPYRIDINE AND SULFATHIAZOLE

Sulfapyridine has been in general use since the fall of 1938, whereas sulfathiazole, a sulfonamide derivative that is similar to sulfapyridine in its range of antibacterial action, has just been released for general use. Very little has yet been reported as to clinical experience with sulfathiazole in large series of cases. Flippin, Schwartz and Rose² recently reported a comparison of results in 100 patients treated with sulfapyridine and 100 treated with sulfathiazole. They considered the effects of the two drugs to be about the same. In a report to the Council on Pharmacy and Chemistry of the American Medical Association, Long⁵ states that early experience indicates that sulfathiazole is about as effective as sulfapyridine in the treatment of pneumococcal pneumonia.

We have treated 37 pneumonia patients with sulfathiazole, alone or in combination with serum. Naturally, no positive conclusion can be drawn from this experience. There was no response to sulfathiazole in 3 patients in whom the administration of sulfapyridine brought about a favorable termination of the infection. It is possible that there may be similar sulfapyridine-resistant cases

that will respond to sulfathiazole, but we have not seen them; we are therefore inclined to believe that sulfapyridine is slightly more effective.

There are unmistakable differences between the two compounds. Sulfathiazole is more rapidly absorbed and excreted in the urine,⁶ and to obtain satisfactory blood concentrations it is therefore necessary to give larger doses. For that reason, the schedule of dosage followed in most of our cases was 3.0 or 4.0 gm. initially, followed by 1.5 gm. every four hours. The blood concentrations achieved tended to vary, much as they do with sulfapyridine, from 1.5 to 15.0 mg. per 100 cc., and equally good therapeutic responses were obtained at different levels. Determination of free sulfathiazole gives an accurate index of the amount present in the body fluids, because very little is conjugated, whereas some patients on sulfapyridine may have a total blood concentration of 10 mg. with a free level of only 2 mg. per 100 cc. Since the conjugated compounds are very insoluble in the urine and much less effective therapeutically, this lack of conjugation is an advantage.

Sulfathiazole has one decided superiority over sulfapyridine in that it is much less apt to cause nausea and vomiting. Almost none of the headache, dizziness, delirium and general malaise that so commonly accompany sulfanilamide administration are seen with sulfathiazole, and cyanosis is minimal. Among approximately 50 patients who have been given sulfathiazole for various infections, we have seen no patients with blood destruction or agranulocytosis, although more cases must be treated to get valid information on this point.

On the other hand, there are two toxic manifestations that we have observed even in our small series. Two women receiving sulfathiazole developed on the extremities skin eruptions that resembled erythema nodosum, although the lesions were not tender. One of them had a conjunctivitis associated with a burning sensation and photophobia. This type of skin rash and conjunctivitis has been described by Haviland and Long.⁷ The most serious toxic reaction we have encountered involved the kidneys and was characterized by a marked diminution in urine output, associated with albuminuria and, in one case, with many granular casts. In a series of 50 cases of various infections treated with sulfathiazole this reaction has occurred four times in 3 patients. One patient was tried on sulfathiazole twice, and each time his urinary output decreased steadily over a period of forty-eight hours, despite a generous fluid intake. Neither sulfanilamide nor sulfapyridine had this effect. In no case did gross or microscopic hematuria or pain, as reported by Arnett,⁸ give any

warning of the danger, but careful check on the output of urine showed that it was rapidly diminishing, and examination of the urine showed albumin. In these patients, the condition cleared fairly promptly when sulfathiazole was discontinued and fluids were forced in large amounts, but high concentrations of sulfathiazole were excreted for the next few days, often enough to precipitate as a yellow dust from the urine, with crystals visible in the sediment. These crystals under the microscope look like radially striated balls or dumb-bells or like sheaves of sticks. It seems conclusive that fluids should be given in liberal amounts during sulfathiazole therapy, and that a careful check must be maintained on the output of urine. This is particularly true when sodium sulfathiazole is given intravenously to achieve rapidly a high blood concentration. We have without mishap used single intravenous injections of 4 gm. of sodium sulfathiazole in distilled water, given slowly as a 5 or 10 per cent solution, in several patients at the start of therapy. Our limited experience with sulfathiazole seems to be in entire agreement with the larger experience of Long and his associates.⁹

One point noted by Flippin, Schwartz and Rose,² which was also true in our cases, is that sulfapyridine appears to bring the temperature down more rapidly than sulfathiazole. We believe, however, that the effect on the temperature may not be a reliable index of the antibacterial action of the two drugs, since we have evidence, experimental and clinical, indicating that sulfapyridine has an antipyretic action.¹⁰ Consequently, a more rapid drop in temperature does not necessarily mean a more effective antibacterial action.

There is little agreement as yet as to the length of time chemotherapy should be continued in the treatment of pneumonia. Long and Wood¹¹ advised continuation of therapy with sulfapyridine (in diminishing doses) until the patient is ready to leave his bed. They stated that there is considerable danger of relapse if therapy is discontinued too soon. Fox, Rosi and Winters¹² urged that sulfapyridine therapy be continued until agglutinins can be demonstrated in the blood, and they reported demonstration of agglutinins in every one of 50 patients studied. On the other hand, there is evidence that demonstrable free antibody is not essential to recovery from pneumococcal pneumonia. Francis and Tillet¹³ studied patients who recovered from pneumonia without any specific treatment, and reported that in some of them no excess of antibody could be demonstrated. Spring, Lowell and Finland,¹⁴ recently reported inability to demonstrate type-specific agglutinins in the blood of some of their sulfapyridine-treated patients during recovery. Kneeland and Mulliken¹⁵

found precipitins in the blood of only 4 of 19 sulfapyridine-treated cases of pneumonia during the recovery phase. Our policy has been to discontinue drug therapy comparatively early. The average duration of therapy in our cases treated with drug alone was 3.6 days for sulfapyridine and 4.0 days for sulfathiazole. In many of these cases, presence of antibodies in the circulation could not be demonstrated by the Francis test at the time therapy was discontinued. Yet in only one case was it necessary to readminister sulfapyridine because of further activity of infection. Early discontinuance of the drug has the advantage of relieving nausea and improving the appetite of most patients, and of decreasing the likelihood of other more serious toxic effects.

INTRAMUSCULAR SEROTHERAPY

Intramuscular administration of serum has been employed successfully in diphtheria for many years, but has been used little in pneumonia. We believe that the intramuscular route of administration has one great advantage that is worthy of consideration: it practically never causes a chill or a thermal reaction. The disadvantage of intramuscular administration is, of course, the fact that absorption of antibody into the circulation is slow, which probably renders this route of administration considerably less effective than the intravenous one when serum alone is employed. However, antibody can be administered by this route fairly satisfactorily, as illustrated by the following case.

CASE 11. J. B. (No. 57216), a 43-year-old man with a Type 1 pneumonia and a history of arrested pulmonary tuberculosis, duodenal ulcer and renal calculi, was admitted on the 3rd day of his disease; one lobe was involved. Blood culture was negative. Because of the presence of renal calculi, it was decided to treat the pneumonia with serum alone. The Francis test was negative. Three hours after admission, the patient was given 60,000 units of concentrated horse serum intramuscularly. Thirteen hours later, the Francis test was still negative, and he was given 150,000 units of serum intramuscularly. Ten hours after the second injection, the Francis test was found to have become positive. Three hours later the temperature was normal. Recovery thereafter was uneventful, and the patient left the hospital on the 11th day.

Finland and Brown¹⁶ studied the absorption of antipneumococcus antibody after intramuscular administration and were able to find antibody in the circulation as early as two hours after administration; the peak of absorption occurred twenty-four to forty-eight hours later. We have administered serum intramuscularly in conjunction with chemotherapy in 20 cases, and have found the results to be satisfactory in most cases. The amounts of serum given at one time varied from 60,000 to 150,000 units. Most of the serums that were given

intramuscularly were known to cause chills when given intravenously, and doses of this size would almost certainly have caused severe thermal reactions if given by the intravenous route; yet there was not a single chill or rise in temperature in this series of cases. Effective absorption of antibody was demonstrated in most cases by the development of a positive Francis test. It should be emphasized that the intramuscular route is not the ideal one, but may be used to advantage with serums apt to give chills or in patients in whom thermal reactions would be dangerous. The dosage may have to be considerably larger, and we have had a few patients in whom the absorption of horse serum so administered was unsatisfactory. However, in severely ill patients, after chemotherapy has been started, a large dose of serum may be given intramuscularly and later be supplemented with smaller doses of intravenous serum.

THE FRANCIS TEST

The Francis test is a valuable guide in the determination of serum dosage,¹⁷⁻¹⁹ and is performed by injecting 0.1 cc. of a 1:10,000 solution of type-specific pneumococcal capsular polysaccharide intradermally. A positive reaction presumably indicates the presence of free antibody in the circulation. It appears in eight to fifteen minutes and is a typical immediate reaction, with erythema and wheal and pseudopodia formation. The advantage of this test is that it tells one within a few minutes whether or not a patient has an adequate supply of antibody. Thus it is a much more rapid, and in many cases, more accurate indication than a fall in body temperature. Although its main usefulness is in guiding serum dosage, the test may also be used in cases treated with sulfonamides alone, since it becomes positive when the natural antibody makes its appearance. Its greatest drawback is the occurrence of false positive reactions in some persons—some patients show a typical immediate skin reaction to the injection of a pneumococcal polysaccharide, although they have no antibody for that type of pneumococcus. In such a person, it would be thought that sufficient serum had been given after the first test. This danger can be eliminated, however, by testing all patients prior to serum therapy. In those who react positively, the Francis test cannot be used.

In the present series of cases the Francis test was used in 42 patients, and in 4 of these a false positive reaction was encountered. In addition, 3 patients never developed a positive reaction at times when there was good evidence that an excess of antibody was present. In the remaining 35 patients the Francis test was a reliable and useful guide.

In regard to the false negative Francis test, that is, failure to react in spite of the presence of excess of antibody in the circulation, it should be pointed out that the skin must possess the capacity to develop a reaction. Some gravely ill patients lack this capacity. One method of testing for it is to inject 0.1 mg. of histamine (0.1 cc. of a 1:1000 solution of histamine phosphate) into the skin. Failure to react to histamine with erythema and a wheal shows that the skin lacks the ability to give a positive Francis test, and one should be so guided.

Details concerning the use of the Francis test.

Once the type of the pneumococcus has been determined from examination of the sputum or blood culture, 1 cc. of a 1:10,000 dilution of the capsular polysaccharide* of this type is withdrawn into a syringe; if the solution is 1:1000, 0.1 cc. is drawn into a syringe containing 0.9 cc. of sterile saline. A single test dose, 0.1 cc., containing 0.01 mg. of polysaccharide, is injected into the skin of the flexor surface of the forearm; 0.1 cc. of sterile saline may be injected in another site to control the patient's reaction to the trauma of injection. If this initial test gives a positive wheal reaction in fifteen minutes or less, it cannot be used as a guide to serum dosage. If the reaction is negative, as it is in most cases, the test can be used as a guide to therapy, and the syringe containing the polysaccharide dilution should be kept at the bedside.

One hour after each intravenous dose of serum the patient should be retested, and if the reaction remains negative, more serum should be given. As soon as a definitely positive reaction is obtained, no more serum need be administered. If the temperature falls, but then rises again, the patient should be retested. If the test has become negative, more serum should be given; if it remains positive, the temperature is not due to a relapse, but to empyema, infection with another type of organism or some other complication, and no more serum of this type is needed. Fever of 101 or 102°F. frequently occurs on the first or second day following serum administration.

If large doses of serum are given and the test remains negative, 0.1 mg. of histamine should be injected intradermally. If this produces no wheal and erythema, it can be concluded that the patient is too ill to give a positive skin reaction to any form of irritation, and the test will not be valid until the patient's condition improves.

It must be emphasized that the test depends on accurate bacteriologic work. If the sputum is wrongly typed, the test means nothing, since the polysaccharide injected is not that of the actual in-

*Solutions of the specific capsular polysaccharides are now commercially available.

fecting type. One should always remember that mixed infections with two pneumococcal types or with pneumococci and hemolytic streptococci may occur, that laboratories are fallible and that if a patient's course is unsatisfactory, another sputum typing and blood culture are indicated.

The practical utility of the Francis test is illustrated by the following case:

CASE 12. A. W. (No. 56518), a 41-year-old man with a Type I pneumonia, was admitted on the 1st day of disease. One lobe was involved. Blood culture was negative.

HISTAMINASE FOR THE PREVENTION OF SERUM SICKNESS

Foshay and Hagebusch¹⁰ recently reported encouraging results in the treatment of serum sickness by the use of histaminase. We were unable to confirm this in the present series of cases. Histaminase* was given both orally and intramuscularly, in doses equal to or greater than those used by Foshay and Hagebusch. The plan followed was to begin therapy with histaminase on the

Therapy with sulfathiazole was begun one hour after admission. The Francis test was negative. Twelve hours later, 60,000 units of concentrated horse serum was injected intramuscularly. Nine hours later the Francis test was still negative, and 60,000 units of serum was injected intramuscularly. Four hours later the Francis test was still negative, and a third dose of 60,000 units of serum was therefore given intramuscularly. Four hours later the Francis test was strongly positive. All therapy, drug and serum, was discontinued. The temperature fell to normal during the next ten hours, but on the next day it rose to 102°F. The Francis test was repeated, and was found to be still strongly positive. With the evidence of excess antibody present in the circulation, it was considered unnecessary to administer more sulfathiazole or serum. This proved correct, since the temperature again fell to normal. The patient's convalescence was impeded by the occurrence of serum sickness, after which he made a good recovery and was discharged on the 24th day.

fifth day following serum administration, and continue it through the tenth day. In the event of development of serum sickness, histaminase therapy was continued until symptoms subsided. As shown in Table 1, there is no evidence that in our cases histaminase had any effect in preventing serum sickness. Its incidence in treated cases happened to be slightly greater than in those patients who did not receive histaminase.

CONCLUSIONS

Experiences in the chemotherapy and serotherapy of pneumonia are reviewed.

Sulfathiazole is comparable to sulfapyridine in

*Histaminase (Torantin) was supplied through the courtesy of the Department of Medical Research, Winthrop Chemical Company, New York City.

its effectiveness against pneumococcal pneumonia. It has the advantage of causing less nausea than sulfapyridine. The urinary output must be carefully watched during its administration, since suppression of urine was the commonest toxic manifestation encountered.

In the majority of cases it is not necessary to continue chemotherapy until the time when liberation of antibodies is expected to take place. Relapse seldom occurs if therapy is discontinued after three to four days.

The combined use of chemotherapy and serotherapy is recommended as the most satisfactory form of treatment in severe pneumonia.

Intramuscular administration of serum has the advantage of avoiding thermal reactions, and in conjunction with chemotherapy it appears to be a practical procedure in many cases.

The Francis test properly controlled is a valuable aid in the estimation of serum dosage.

Histaminase has not been found to have any action in preventing the occurrence of serum sickness.

PAIN ASSOCIATED WITH RENAL APLASIA*

Report of Two Cases

HILBERT S. SABIN, M.D.,† AND GEORGE GILBERT SMITH, M.D.‡

BOSTON

DURING the past year on the Urological Service of the Massachusetts General Hospital we have encountered two rather interesting and unusual cases of pain associated with congenital aplasia of the kidney.

CASE REPORTS

CASE 1. A 14-year-old girl was first seen in the Emergency Ward on July 26, 1939, complaining of frequent episodes of cramplike, right-sided abdominal pain of 6 weeks' duration. The pain was occasionally associated with epistaxis, headache, anorexia and malaise. Two days before admission, the attacks became more frequent, and the pain assumed a sharp, lancinating character, radiating to the right lower quadrant. There was slight burning and frequency on micturition, and nocturia thrice. Pain was aggravated by walking, running and stooping, and was somewhat alleviated by pressure over the tender area in the right upper quadrant.

*From the Urological Service, Massachusetts General Hospital. Presented at a meeting of the New England Section of the American Urological Association, Boston, May 2, 1940.

†Formerly, resident in urology, Massachusetts General Hospital.

‡Associate in urology, Harvard Medical School; chief of Urological Service, Massachusetts General Hospital.

Physical examination revealed moderate right costo-vertebral tenderness and diffuse tenderness in the right flank and right upper quadrant. Urinalysis was negative. The leukocyte count was 10,000, the blood pressure 116/65. The nonprotein nitrogen of the blood serum was 17 mg. per 100 cc. The temperature, pulse and respirations were normal. An intravenous pyelogram revealed a hypertrophic, normally functioning left kidney that was incompletely rotated (Fig. 1). No kidney was visible on the right, and there was no excretion of dye on that side. Cystoscopy showed a normal bladder and normal ureteral orifices. The right ureter was catheterized, and obstruction encountered 24 cm. from the bladder. Skiodan was injected and failed to reveal a kidney on that side, the dye returning down the ureter. It was thought that the patient probably had a cut-off aplastic right kidney, but that this was not responsible for her pain.

The patient was discharged and returned six weeks later with a story of recurrent attacks of pain. Physical and laboratory findings were unchanged. Extensive studies were carried out, including a gastrointestinal series, barium enema, Graham test and psychiatric and orthopedic consultations, all of which revealed no evidence of disease. The x-ray films were reviewed, and it was

believed that the patient's symptoms might be due to the presence of a horseshoe kidney with a cut-off right segment. Because other evidence of disease was lacking, it was decided to explore the right kidney.

At operation, what appeared to be a normal ureter was

fat and fibrous tissue measuring 8 by 4 by 2 cm.; the mass contained numerous gray, smooth, transparent cysts measuring up to 3 cm. in diameter and containing a clear, straw-colored fluid. On section the cut surface presented a firm gray fibrous appearance, with no normal kidney tissue.

The microscopic report was as follows:

Scattered through a dense fibrous-tissue stroma, there are large and small tubular structures, some slightly papillary, lined by a layer of cuboidal epithelium; in many places these have smooth muscle walls. These tubules are very probably remnants of the Wolffian ducts. There are also many smaller tubules, some filled with pink-staining casts, which are very similar to the colloid filled tubules seen in chronic pyelonephritis. No definite glomeruli are identified. The stroma in places is very vascular (Fig. 2).

Convalescence was uneventful. The patient was discharged in good condition on the 11th postoperative day. She has been followed in the Out Patient Department for 3 months and is entirely asymptomatic so far as her former complaints are concerned. She is in excellent general health.

CASE 2. A 25-year-old store clerk was admitted to the Urological Service of the Massachusetts General Hospital because of pain in the left back of 2 years' duration. The pain was dull and aching and was localized to the left costovertebral region. It was exaggerated by bending forward and was almost constantly present.

Physical examination was entirely negative except for moderate left costovertebral tenderness. A gastrointestinal series done 9 months before admission was reported negative. On excretory pyelography, there was prompt ex-

observed. When freed up, this was found to be under tension and to degenerate into a fibrous cord attached above to a rounded body, 8 cm. in length, that consisted

FIGURE 2.

of a mass of smooth cysts filled with clear fluid. There was a definite artery running to the mass from the region of the aorta. This was tied and cut, and the cystic body, with the ureter as far as the pelvic brim, removed. The pathological report described an irregular mass of

cretion of the intravenous dye from the right side, filling a slightly dilated pelvis and ureter (Fig. 3). There was a very questionable kidney shadow on the left, with no excretion of the dye on that side in 60 minutes. Cystoscopy revealed a normal bladder and normal ureteral orifices.

A ureteral catheter engaged in the left orifice but could not be passed farther than 5 cm, and no dye could be injected past this obstruction; a catheter was easily passed to the right kidney, and a normal drip of clear urine ob-

FIGURE 3.

tained (Fig. 4). Since the patient was unable to carry on his work because of the discomfort, it was decided to explore the left renal region on the possibility that the pain was due to an atrophic blocked kidney.

At operation no ureter was seen, but in its place was a fibrous cord that terminated about the level of the 2nd lumbar vertebra. Exploration of the renal fossa revealed a small, flat, brownish body measuring 5 by 4 by 1 cm. and studded with 4 or 5 small purplish cysts. This mass was attached to a fibrous pedicle that contained several small sclerotic vessels. The pedicle was clamped, cut and tied, and the mass removed in toto. What appeared to be a normal adrenal gland was felt above this body. A diagnosis of aplastic kidney was made by the pathologist. Microscopic examination revealed findings similar to those of Case 1. The tubules, however, were much larger and more numerous, and the colloid-filled small tubules less conspicuous; no glomeruli were observed (Fig. 5).

The postoperative course was uneventful. The wound healed by first intention, and the patient was discharged entirely asymptomatic on the 11th postoperative day. At the present time, 5 months after operation, he has had no recurrence of his previous symptoms and is in excellent health.

These two cases exemplify congenital defects or arrest in development of one kidney associated with hypertrophy of its mate. They are differentiated from congenital hypoplasia of the kidney in that at no time have they possessed excretory function. The etiology of the pain in both cases is rather obscure; it may perhaps be explained by the pressure of the cystic bodies on the surrounding tissues, or as in the first case, by tension on the obliterated ureter.

This rare condition has been observed occasionally at post-mortem examination. Campbell¹ reported 39 cases of renal aplasia in a series of 13,000

FIGURE 4.

autopsies at Bellevue Hospital and claimed that its incidence is four times that of congenital absence of the kidney.

Clinically this condition is seldom encountered. MacKenzie and Hawthorne² reported three cases similar to the above in which excision of a cystic aplastic kidney produced permanent relief of symptoms. Gutierrez,³ in an interesting discussion of the developmental defects of the kidney, postulates the following conditions in true renal aplasia: no true kidney; no evidence of pelvis; absence of true renal pedicle; renal artery small or absent; ureter incompletely developed and not patent; no excretion of urine; no renal function; bladder with

no normal ureteral orifices or one ectopic ureter; histologic section of the supposed renal mass reveals glomeruli and tubules showing arrest in the development of the renal organ; cystoscopy, catheterization of the ureters and descending or as-

substance, although no definite kidney outline could be seen.

CONCLUSIONS

Abdominal pain in certain rare cases is associated with congenital aplasia of the kidney;

FIGURE 5.

ending pyelography are necessary for diagnosis of the condition. This author reports two cases of renal aplasia. In one, the preoperative diagnosis was made by observing four small pea-sized shadows in the excretory urogram that gave the impression that the dye had been excreted by some kidney

surgical intervention results in complete relief of symptoms.

INTUSSUSCEPTION OF THE JEJUNUM DUE TO CARCINOID TUMOR

SAMUEL MUFSON, M.D.,* AND EDWARD A. HOROWITZ, M.D.†

NEW YORK CITY

ABOUT 75 per cent of the cases of intussusception occur in children under two years of age,¹ although a specific cause for the production of the invagination in children is usually not found. Perrin and Lindsay² found only 18 patients over fourteen years of age in a series of 314 cases collected at the London Hospital from 1903 to 1920.

In adult cases of intussusception, a tumor is the commonest etiologic agent. Eliot and Corscaden,³ in their analysis of 300 cases of intussusception in adults, found a tumor of the bowel in 40 per cent of the cases, of which the greater number were benign. Other causes were ulceration of the bowel of tuberculous, bacillary or typhoid origin in 14 per cent, and a Meckel's diverticulum in 12 per cent. Among the tumors usually found were polyps, leiomyomas, lipomas, fibromas and carcinomas.

Tumors of the small intestine are relatively infrequent as compared with tumors of the other parts of the gastrointestinal tract. Raiford⁴ in 1932, in a very full discussion of tumors of the small intestine, reported a series of 88 cases found among 11,500 autopsies and 45,000 surgical specimens at the Johns Hopkins Hospital. He was also able to collect from the literature 339 tumors of the small intestine that he considered authentic. The 88 cases comprised 8.9 per cent of the total number of gastrointestinal tumors, which was 986. The 50 benign and 38 malignant small intestinal tumors comprised 23.8 per cent and 4.9 per cent respectively of the total benign tumors (210) and total malignant tumors (776) of the gastrointestinal tract. The benign tumors included adenomas, fibromas, myomas, lipomas, angiomas, pancreatic rests, hemangiomas, argentaffin (carcinoid) tumors and cysts. In this series the carcinoid or argentaffin tumors numbered 7, and were all benign.

Tumors of the small intestine often produce no symptoms, and are found only incidentally at autopsy. The symptoms that they do produce are usually the result of obstruction of the intestine, incomplete or complete, or of the production of an intussusception.

Freilich and Coe⁵ were able to collect from

the literature a total of 3284 cases of intussusception, of which 462 were enteric; and of these, 24 were jejunal. Altogether, from 1852 to 1934, 29 recorded cases of jejunal intussusception occurred in patients from four months to sixty-seven years old, with an average age of 27; 15 cases were in men, 13 in women, and 1 not specified; 18 were of a simple jejunojejunal type, 9 were double jejunal, and 2 were triple jejunal. The majority were caused by such tumors as polyps, lipomas and papillary adenomas. No case of jejunal intussusception due to a carcinoid tumor was listed.

No specific character of the carcinoid tumor, as compared with other tumors, makes it less likely to produce an intussusception. The relative rarity of carcinoid tumors probably accounts for the paucity of such occurrences. In 1930, Cooke⁶ collected from the literature 104 cases of carcinoid tumor of the small intestine, and added 11 of his own. Ariel,⁷ in the most recent review of the subject, found 111 cases in the literature since 1930, and reported 11 additional cases, thus making the total of reported cases 237.

Among these 237 carcinoid tumors, only 3 cases of intussusception occurred. These were reported by McGlannan and McCleary,⁸ Jones⁹ and Ariel.⁷ In all 3 the tumor was located in the ileum.

Because of the extreme rarity of its occurrence, a recent case of intussusception of the jejunum due to a carcinoid tumor is worth reporting.

Since no new features of pathologic histology appeared in this case, no lengthy description of carcinoid tumors will be given. During the last thirty years, since the name "carcinoid" was given to these tumors by Oberndorfer,¹⁰ a considerable literature has accumulated on the subject. Excellent contributions to and reviews of the problems of pathogenesis have appeared, together with adequate descriptions of the clinical features; for these the reader is referred to the papers of Masson,¹¹ Forbus,¹² Cooke,⁶ Raiford,¹³ Bailey,¹⁴ Humphreys¹⁵ and Ariel.⁷ The work of Masson, particularly, has thrown light on the origin of these tumors from the Kultschitzky cells in the wall of the crypts of Lieberkuhn and on the relation of these cells to those of the chromaffin system and to the nerve plexuses of the intestinal wall. The demonstration of the identity of the

†Associate gynecologist, Beth Israel Hospital.

silver-staining granules in the cells of these tumors with those in the Kultschitzky cells was chiefly due to the researches of Masson, and the term "argentaffin tumor" as a synonym of carcinoid tumor was therefore introduced.

These yellowish tumors were referred to as carcinoids by Oberndorfer¹⁰ because of their superficial similarity to true carcinoma. They were at first considered to be essentially benign. But as increasing numbers were reported, many cases with unmistakable metastasis were found, as evidenced by extension to the regional lymph nodes, mesenteric fat and liver. In Cooke's⁶ series of 115 cases, 21, or 18 per cent, had metastasized. In Ariel's⁷ series of 111 reported cases, 33, or 30 per cent, had metastasized, and among his own 11 cases, metastases were found in 5. Thus, metastases occurred in 59, or 25 per cent, of the 237 cases recorded to date.

The decision as to where the line should be drawn between benignity and malignancy in these tumors is a difficult one, except when metastases actually occur. Thus Humphreys¹¹ states, "The small submucous nodule is certainly a clinically insignificant lesion, and yet it already shows an infiltrative manner of growth which, in a gland cell tumor, is one of the criteria of malignancy." This tendency to invade the muscle and serous layers of the intestinal wall, and to extend out into the mesentery, warrants a diagnosis of carcinoma even in the absence of demonstrable metastases in the lymph nodes or liver. Furthermore, even in the absence of invasive features, the appearance and arrangement of the cells may suggest carcinoma to the experienced pathologist.

In most cases, carcinoid tumors are of slow growth, and are slow to metastasize. This lends a good prognosis to cases that have produced early clinical manifestations, and resection is likely to be followed by favorable results. That the carcinoid tumor is a far from harmless lesion, however, is emphasized by Ariel,⁷ who found that of 38 patients with clinical symptoms produced by carcinoid tumors, 14 died as the result of the tumors or their metastasis, or of attempts at extirpation. Of the 38 patients, 13 were subjected to resection, and were well for varying periods.

Resection is the treatment of choice. The value of x-ray therapy has not yet been evaluated, although the recession of a local recurrence in one case led Ariel to believe that these tumors might be radiosensitive.

CASE REPORT

M B, a 19-year-old girl, was admitted to the Beth Israel Hospital on May 5, 1939. The past history was noncontributory.

About two weeks prior to entry she had had a sudden onset of epigastric colicky pain and vomiting, which continued intermittently for the next 3 days. Enemas afforded temporary relief. Subsequently the patient seemed well until 11 a.m. of the day of admission, when she was again suddenly seized with severe colicky pain in the epigastrium, and to the left of the umbilicus. She vomited 3 times, and complained of persistent nausea. The bowels moved once.

On examination, the patient appeared pale, and in obvious distress from severe pain. The abdomen was not distended, but a rounded fullness was visible just to the left of the umbilicus. Palpation at this site revealed a mass that was rounded in shape, about the size of an orange, tensely elastic, immovable and moderately tender. There was no tenderness elsewhere in the abdomen, and the abdominal wall was generally soft. Pelvic and rectal examinations were negative. The temperature was 98.6°F, the pulse 80, and the blood pressure 134/85.

Examination of the blood showed a red cell count of 4,340,000, with 90 per cent hemoglobin, and a white cell count of 13,000, with 85 per cent segmented polymorphonuclears, 5 per cent young polymorphonuclears, 8 per cent lymphocytes and 2 per cent monocytes. The urine was normal. The sedimentation rate was 7 mm in 45 minutes. Examination of the stools revealed no blood.

The preoperative diagnosis was acute intestinal obstruction, due either to a strangulated paraduodenal hernia or to an intussusception.

Operation was performed about 8 hours after the onset of acute pain. Under spinal anesthesia, a 5 inch left paramedian muscle splitting incision was made. When the peritoneum was opened, a large sausage shaped mass of intestine, fully 10 cm in diameter and over 30 cm in length, was found occupying the epigastrium and left paraumbilical region, it appeared purplish, and exceedingly tense. The entire mass was delivered from the wound. It was identified as a jejunojejunal intussusception. The terminal portion of the mass abruptly changed to collapsed, narrow jejunum. At the proximal end, the intussuscepted jejunum was markedly constricted, and the accompanying mesentery appeared twisted, edematous and ecchymotic. Reduction of the intussusception was effected after considerable difficulty, rupture of the distended, thinned-out intussuscepted bowel being a constant hazard. After reduction, the intussuscepted bowel was found to be the site of a tumor, readily visible at a constricted, retracted segment of the intestine and showing a depression or umbilication on the serosal surface. Palpation revealed a firm mass, about 5 cm in diameter. The mesentery proximal to the tumor had accompanied the intussuscepted intestine, and as a result appeared traumatized, ecchymotic and edematous, with some question of the patency of its blood vessels. There were numerous enlarged, but soft, lymph nodes in this portion of the mesentery. No metastases in the liver or omentum could be seen or felt.

The entire intussuscepted length of intestine, including the tumor and the involved mesentery, was resected, altogether about 20 cm. The ends of the divided jejunum, held by Payr clamps, were closed with an inverting suture of chromic catgut and two purse string sutures of Pagenstecher linen. The two portions of jejunum were then apposed, the closed ends adjacent to each other, and a side-to-side anastomosis made in the usual manner, using chromic catgut for the through and through suture, and Pagenstecher linen for the outer serosal suture. The bowel was then returned to the peritoneal cavity,

and the abdominal wound closed in layers, without drainage.

The pathological report by Dr. Alfred Plaut was as follows:

The resected specimen of the jejunum is 20 cm. long. About 3.5 cm. from the one end, on the antimesenteric side, the lumen is almost occluded by a flat, ovoid, irregular, mushroom-shaped formation, 5.3 by 3.0 by

FIGURE 1. *Gross Specimen.*

Flat, ovoid, mushroom-shaped tumor occluding the lumen of the jejunum.

1.0 cm. [Fig. 1]. Somewhat eccentrically, there is a depression in the center of which a small elevation is situated. The depression measures 1.7 by 1.2 cm.

The surface of the tumor in general is smooth and finely granular, with some brownish material adherent to it. There is one small, ovoid, deep-red elevation at the edge. The mucosa directly outside the tumor appears normal. There is very little thickening of the muscle coat. The mucosa in the remainder of the specimen is hyperemic and edematous. No ulceration or necrosis is seen with the naked eye.

On the outside, corresponding to the tumor, the serosa is partly yellowish, partly cyanotic. There is an irregularly ovoid transverse depression. The serosa has lost its sheen throughout. The cut edge of the tumor is homogeneously grayish (after fixation).

Microscopically, the tumor tissue is entirely necrotic on the surface, and considerably necrotic throughout, so that proper cytological studies cannot be made. The cells are not very closely packed. The stroma contains very few cells except those due to the inflammatory reaction caused by the necrosis. There are few blood vessels.

The tumor is situated chiefly in the submucosa, but the mucosa is widely invaded [Fig. 2]. The muscle coat is partly destroyed by the tumor. In the muscle coat a linear arrangement of the tumor cells is distinct. The cells are medium sized, with large nuclei [Fig. 3].

Many fragments of nuclei are seen in the necrotic areas. None of the lymph nodes contain tumor.

Diagnosis: malignant carcinoid.

The patient's postoperative course was uneventful. She was treated immediately with an indwelling Levine

FIGURE 2. *Low-Power Magnification.*

was started on the 2nd postoperative day, and sulfanilamide discontinued at the end of the 3rd day, a blood concentration of 5.5 mg. per 100 cc. having been obtained.

Except for drowsiness, cyanosis and moderate nausea attributable to the sulfamidamide, the subsequent course was entirely uncomplicated. The abdomen was soft and not distended. The temperature rose to 102.2°F on the day following operation, and thereafter gradually descended to normal on the 6th day.

The wound healed by primary union. The patient was up and about for several days, and was discharged from the hospital on the 17th postoperative day.

When last examined, 8 months after operation, the patient was quite well. Except for three or four occasions when she experienced moderate abdominal dull pain and discomfort with no associated nausea or vomiting, which were quickly relieved by enema, she had had no symptoms suggesting any disorder related to the disease for which she was operated on. Physical examination was entirely negative, the operative scar was firm, and the abdomen was soft and nontender throughout, with no palpable organs or mass.

CONCLUSIONS

Cases of intussusception due to carcinoid tumors are extremely rare.

The case reported appears to be the first record of a carcinoid tumor causing an intussusception of the jejunum.

Carcinoid tumors are more frequently malignant than has been usually assumed, although the rate of progression is slow.

Resection of the involved intestine offers an ex-

cellent prognosis for permanent cure, in the absence of distant metastases of the lymph nodes or liver.

MEDICAL PROGRESS

ENDOSCOPY*

EDWARD B. BENEDICT, M.D.†

BOSTON

SINCE there have been several recent articles in the *Journal* on gastroscopy (Benedict,¹ Jankelson and McClure²) and peritoneoscopy (Benedict,³ Garrey⁴), this report is confined to a review of the present status and recent progress in bronchoscopy and esophagoscopy, perhaps better termed "bronchoesophagology" (Jackson⁵).

BRONCHOSCOPY

Bronchoscopic examination was originally developed, and during the early years was performed, for the purpose of removing foreign bodies from the tracheobronchial tree. With increased knowledge of pulmonary disease and greater experience in thoracic surgery, however, bronchoscopy has become of major importance in the diagnosis and treatment of intrapulmonary disease. Ap-

proximately only 2 per cent of the bronchoscopies now performed are for the removal of foreign bodies.

Technic

The *sine qua non* of successful bronchoscopy is good teamwork, for with it bronchoscopy is comparatively easy; without it the procedure may be extremely difficult or impossible. When bronchoscopy is made easy, internists and surgeons will request it with almost as little thought as ordering an x-ray examination, and will refer to it as "slipping down a bronchoscope"; when clumsily performed, however, it will seldom be requested a second time, for physicians will not "put their patients through it." Good teamwork means not only a skillful operator but also an experienced head holder and a well-trained nurse in charge of the instruments. Changes in personnel are

*From the Massachusetts General Hospital.

†Assistant in surgery, Harvard Medical School; assistant surgeon, Massachusetts General Hospital.

disastrous. Bronchoscopic equipment is delicate and requires constant supervision by experts, for defective apparatus cannot be corrected after the bronchoscope has been introduced. In adults, a preliminary sedation is used with cocainization of the throat; in children, no anesthesia is used. New instruments have been repeatedly designed for special uses by the Jacksons⁶ and others, but in general the technic and equipment are well standardized. The use of the telescopic bronchoscope (Pinchin and Morlock,⁷ Wolfson and Schloss⁸) has permitted in many cases a clear view into the upper-lobe bronchi. The telescope is passed through the standard bronchoscope, and since its objective lens permits vision at right angles to the axis of the instrument, a view can be obtained into an otherwise inaccessible bronchus. If a lesion is visible, the curved flexible forceps may then be passed to obtain a specimen of tissue.

Anatomy

The nomenclature of the various bronchopulmonary divisions and segments has become of great importance to the bronchoscopist and thoracic surgeon, especially since Churchill's⁹ pioneer work on segmental lobectomy. Recent studies have been reported by Neil, Gilmour and Gwynne.¹⁰ Further attempts to standardize the nomenclature are in progress at the Massachusetts General Hospital (Adams and Davenport¹¹). Davis¹² has discussed anatomic variations of the normal tracheobronchial tree.

Use in Various Diseases

Bronchiectasis. The diagnosis of bronchiectasis is usually established by the clinical history and x-ray examination after the instillation of iodized oil. Bronchoscopy is indicated when the question of foreign body arises. Hemoptysis, although a frequent symptom in uncomplicated bronchiectasis, may indicate the presence of a benign or malignant tumor partially blocking the bronchus. Although some evidence of tumor is usually present by physical signs or x-ray examination, bronchoscopy is indicated in doubtful cases. At the conclusion of the procedure, a catheter may be placed in the trachea and iodized oil instilled. This method of bronchography has proved more satisfactory than direct instillation through the bronchoscope. Once a diagnosis of bronchiectasis has been established, the treatment, if possible, is lobectomy. When, however, the disease is too extensive or the patient is a poor operative risk, palliative treatment is given by repeated bronchoscopic aspiration. By this method the patient is relieved of large amounts of foul, partially stagnant secretions, is able to breathe better, raises his secretions

more easily and gains in weight and strength. When large amounts of foul stagnant secretions are present, bronchoscopy is indicated as a preliminary procedure to lobectomy.

Chronic cystic disease. The indications for bronchoscopy in this disease are much the same as in bronchiectasis. In the inoperable cases, striking improvement is seen after bronchoscopic aspirations repeated about every two weeks.

Asthma. Bronchoscopy in asthma has proved of value in diagnosis and treatment. With regard to diagnosis it should be emphasized that although wheeze is a common symptom in asthma, it occurs in other pulmonary diseases, notably carcinoma, benign tumor and foreign body. Clerf¹³ has reported cases with apparent asthmatic wheeze due to carcinoma of the bronchus and foreign body in the esophagus. Whenever any doubt exists, bronchoscopy should be performed. In the treatment of asthma, the procedure has been useful in the aspiration of excessive secretions. Repeated aspiration may be necessary. When atelectasis is present, the bronchoscopic removal of tenacious secretions from the orifice of the involved bronchus may result in re-expansion of the lobe. Bronchostenosis, characterized by febrile episodes, occurred in 68 per cent of the asthma cases recently reported by Prickman and Moersch.¹⁴ In many of these cases, x-ray examination was negative. At bronchoscopy a stenotic bronchus may be visualized and dilated, with aspiration of thick, tenacious secretions. Vaccine made from bronchoscopically removed secretions has been reported to be of value in cases of bacterial allergy.

Chronic bronchitis. Many patients come to the physician because of hemoptysis without other symptoms. In some of these patients, physical examination and complete x-ray study are negative. Bronchoscopy reveals a slightly red, sometimes edematous, friable, easily bleeding mucosa in one or more parts of the tracheobronchial tree. When this mucosa is touched gently with the tip of the bronchoscope, abnormally free oozing of blood occurs. Such a finding accounts for repeated small hemoptyses in these patients. The cauterization of such areas with 5 per cent silver nitrate is apparently of some benefit. Although this disease is not chronic bronchitis in the ordinary sense of the term, it probably represents a mild inflammatory state of the bronchial mucosa.

Acute laryngotracheobronchitis (Richards¹⁵) is a very serious respiratory disease of children and carries a high mortality. It is characterized by edema, desquamation, and the formation of sticky gelatinous crusts, which cause bronchial obstruction with atelectasis. Tracheotomy may be neces-

sary for laryngeal obstruction, and repeated bronchoscopies are required for the removal of obstructive material.

Diffuse polypoid laryngotracheobronchitis (Samson²⁴) is a rare condition characterized by inflammatory polypoid mucosal changes possibly secondary to chronic pulmonary suppuration. Special bronchoscopic curettes have been designed by Samson for rapid removal of the obstructing tissue.

Broncholithiasis, the formation of one or more calcareous deposits in the bronchial tree, is a rare condition and is probably the result of inflammation in the bronchus or erosion of a calcareous peribronchial lymph node. Cough, hemoptysis, wheeze and signs of bronchial obstruction may be present. Bronchoscopy is indicated for accurate diagnosis and removal of the broncholith.

Postoperative pulmonary complications. Postoperative atelectasis frequently clears up spontaneously after severe coughing and changes in the patient's position. When, however, re-expansion does not take place promptly, bronchoscopy is indicated to remove thick tenacious secretions plugging the bronchial orifice. By securing prompt re-expansion of the lobe under such conditions, one may prevent more serious pulmonary complications. Gius²⁷ has recently reviewed this subject in detail, stating that bronchoscopic aspiration has been repeatedly used with gratifying results. Anesthesiologists (Beecher,²⁸ Mousel,²⁹ Eversole³⁰) are becoming increasingly aware of the value of tracheobronchial aspiration during and after anesthesia.

Lung abscess. Bronchoscopy is indicated in lung abscess to exclude or remove foreign bodies, to localize exactly the abscess in a particular pulmonary segment, to aspirate secretions and to improve drainage from the abscess cavity. Bronchoscopy sometimes discloses an unsuspected neoplasm in addition to the abscess. Bronchoscopic treatment of lung abscess should be reserved primarily for abscesses that are accessible to the major bronchi. Appropriate medical measures must also be instituted, including rest in bed, adequate diet and postural drainage. If an early response to medical and bronchoscopic treatment is not obtained, surgery is indicated. The management of lung abscess should therefore be in the hands of the internist, roentgenologist, bronchoscopist and thoracic surgeon.

Malignant tumor. The frequency of primary carcinoma of the lung is apparently increasing. A presumptive diagnosis may often be made from the history of cough, hemoptysis and weight loss, together with the physical signs and x-ray find-

ings. A positive diagnosis can be made in about 75 per cent of the cases by bronchoscopic biopsy, and the exact location of the tumor is established. Only by knowing as closely as possible the exact site of the lesion can the proper procedure—lobectomy, pneumonectomy or x-ray therapy—be determined. Removal of large amounts of cancer tissue by bronchoscopy may occasionally be of temporary benefit in improving the airway. The introduction of radon seeds through the bronchoscope is of little value compared to x-ray treatment. If lobectomy or pneumonectomy is not indicated, marked relief of cough, pain and hemoptysis is sometimes obtained by x-ray therapy, particularly in the oat-cell or highly malignant cancers. When life is prolonged over two years by any type of nonsurgical therapy in carcinoma, one must seriously question the diagnosis, for benign adenoma may simulate adenocarcinoma. Metastatic tumors to the lung seldom invade the major bronchi. When they do on rare occasions obstruct a major bronchus, improvement in the airway may be obtained by bronchoscopic removal and x-ray therapy. In the present state of knowledge, the only hope of cure in cancer lies in early diagnosis. For this reason, it is important to perform bronchoscopy early when bronchogenic carcinoma is suspected.

Benign tumor. Adenoma is undoubtedly the commonest benign tumor of the bronchus. Although the history of long-continued hemoptysis in a young patient, in addition to the physical signs and x-ray findings, may lead to a probable diagnosis of adenoma, atypical cases occur frequently enough to make a positive diagnosis possible only by bronchoscopy. When the bronchoscopist sees a smooth rounded tumor mass in the bronchus, he may be reasonably sure that he is dealing with a benign tumor, but sometimes a fairly smooth fingerlike process from a carcinoma may project upward into the bronchus and may be confused with a benign tumor. Bronchoscopic biopsy leads to a positive microscopic diagnosis. If the case is one of benign tumor and irreparable lung damage has not already occurred as a result of bronchial obstruction, bronchoscopic removal of the tumor is indicated. This may require several bronchoscopies, and the site of the tumor should be inspected subsequently at regular intervals to detect possible recurrence. Although a considerable portion of the tumor may lie outside the bronchus, it is nonmalignant, and the patient is entirely relieved by bronchoscopic removal. If irreparable lung damage has occurred and the patient's symptoms and general condition warrant it, lobectomy or pneumonectomy is indicated.

Tuberculosis. Tracheobronchial tuberculosis is encountered with increasing frequency and is therefore of great importance. Its apparent increase is probably due largely to the more frequent use of the bronchoscope. It occurs in approximately 10 per cent of the cases of pulmonary tuberculosis. The old fear that bronchoscopy might cause a spread of the lesion has not been borne out by hundreds of bronchoscopic examinations in various stages of the disease. A persistently positive sputum in the face of essentially negative or minimal x-ray findings may be explained by the bronchoscopic demonstration of ulcerative or proliferative bronchial lesions. Such lesions may heal after the application of silver nitrate, but the fact that they have also been observed to heal spontaneously with probable equal frequency gives little encouragement to the use of intrabronchial applications. Unfortunately these lesions usually do not heal but tend to increase in size, to appear in other locations and to produce bronchial obstruction. In selected cases during the acute congestive stage, x-ray treatment is of benefit (Davenport²¹). Fibrous stenosis from old tracheobronchial tuberculosis may cause symptoms of intermittent bronchial obstruction, namely, cough, fever and malaise, with inability to raise sputum. In such cases, gentle dilatation of the stenosis by soft bougies may relieve the obstruction and cause marked improvement. Bronchiectasis may develop distal to the stenosis. In general, the prognosis of active tracheobronchial tuberculosis is bad. Occasionally tuberculous lymph nodes may by extrinsic pressure on the trachea or bronchi cause partial obstruction. Such lymph nodes may erode the bronchial mucosa, enter the bronchus and cause complete obstruction; they should be removed bronchoscopically.

The following are the indications for bronchoscopy in tuberculosis: obstructive symptoms, that is, atelectasis, wheeze, difficulty in raising sputum, persistent cough or dyspnea out of proportion to the amount of pulmonary disease, periodic intermittent febrile attacks and x-ray evidence of bronchial narrowing; positive sputum when parenchymal disease is controlled or absent; hemorrhage in the absence of sufficient pulmonary disease to explain the source; proposed collapse therapy in those in whom there is any question of tracheal stenosis or stenosis of the contralateral bronchi.

Sarcoid. Pulmonary sarcoidosis is not uncommon. Bronchial involvement by sarcoid was first reported, however, in a recent paper by Benedict and Castleman.²² In this case, the signs and symptoms of bronchial obstruction were the important

features. Bronchoscopy showed extensive intrinsic involvement of the bronchial mucosa. A bronchoscopic biopsy showed the characteristic histology of sarcoid without evidence of tuberculosis. Treatment through the bronchoscope resulted in marked improvement.

Foreign body. Although representing only a small proportion of the work in any bronchoscopic clinic, the removal of foreign bodies is still probably the most dramatic work of the bronchoscopist. Since instruments exist for the removal of all sizes and shapes of vegetal and metallic foreign bodies in children as well as in adults,—not only from the major lower-lobe bronchi but also, with the aid of the biplane fluoroscope and the costophrenic bronchoscope, from the upper lobe and terminal bronchi,—it is evident that few foreign bodies are beyond bronchoscopic removal. Although all foreign bodies should be promptly removed, some metallic foreign bodies have been known to remain in the bronchi for a number of years and, in the absence of bronchial obstruction, to have caused comparatively little lung damage. Since all vegetal substances cause violent mucosal reactions, frequently with complete bronchial or even tracheal obstruction, their removal constitutes a real emergency. A bronchoscopic clinic should, therefore, be in a state of complete preparedness for any emergency.

ESOPHAGOSCOPY

Technic

The same considerations apply here as were emphasized in the paragraph on bronchoscopic technic. Particularly important is the avoidance of general anesthesia, which is not only unnecessary and more dangerous than local anesthesia but also likely to limit the frequency with which the procedure will be requested.

Use in Various Diseases

Carcinoma. This is by far the most important disease of the esophagus. The first symptom is difficulty in swallowing solid food. Regurgitation of food, saliva and blood is common. Difficulty in swallowing liquids is a late symptom. Pain, if present at all, is usually noted only in the late stages. For an early diagnosis of carcinoma of the esophagus, every patient complaining of dysphagia should have immediate x-ray examination. The x-ray diagnosis of esophageal carcinoma is highly accurate, but confusion has sometimes occurred with benign stricture and with cardiospasm. Esophagoscopy is indicated in every case of suspected cancer of the esophagus. A biopsy can be obtained and the diagnosis thus positively estab-

lished, with grading of the type and degree of malignancy. Moreover, the esophagoscopist may be able to give useful information to the thoracic surgeon regarding possible fixation of the growth. Because of recent advances in the technic of esophagectomy, it is imperative that the diagnosis be established early. I have recently seen two comparatively young patients (forty-two and fifty-seven years of age) in whom the history and x-ray findings were those of carcinoma, but in whom esophagoscopy at another hospital failed to reveal the tumor. These patients were treated for benign stricture until a subsequent esophagoscopy demonstrated carcinoma, when it was too late to operate. Under such circumstances the important thing is to perform repeated esophagoscopies until no doubt remains as to the correct diagnosis.

Many patients, unfortunately, are seen so late in the disease or are such poor surgical risks that operation is not indicated. Much can be done, however, to keep these patients comfortable. The lumen of the esophagus can be kept open by bouginage and x-ray treatment, and since everyone prefers feeding by mouth to being fed by gastrostomy tube, this is very important and saves many needless gastrostomies. Whenever during the course of the disease or as a temporary result of x-ray treatment the lumen of the esophagus becomes so narrowed that only liquids are tolerated, the patient should be instructed to swallow a thread over which bougies may be passed. After about 15 feet of thread has been swallowed, it becomes securely anchored and serves as a guide for the passage of bougies. There is, of course, some danger in stretching an esophagus invaded by cancer, but the risk is worth taking under these circumstances, and in my experience there have been no accidents. I have under my care a young patient with carcinoma of the esophagus (recognized too late for esophagectomy) who could barely swallow liquids on admission but who now can eat normally as a result of bouginage and x-ray treatment. Although he will ultimately succumb to the disease, he is leading a fairly normal life and has returned to work. Such palliative results are definitely worth while.

Benign tumors of the esophagus are exceedingly rare. Patterson,²³ in 1932, was able to find reports of only 61 cases in the literature. Among these are included adenomas, fibromas, lipomas, angiomas, papillomas, leiomyomas and myxomas. The symptoms are usually dysphagia and regurgitation. X-ray examination should show the location of the tumor. Esophagoscopy is necessary for biopsy and removal.

Cardiospasm. This diagnosis is usually made

by history and x-ray examination, but in doubtful cases esophagoscopy is occasionally indicated to rule out carcinoma. Although drug therapy and psychotherapy are sometimes of benefit, the most striking improvement usually follows dilatation with mercury bougies. This may have to be repeated at varying intervals. Occasionally in intractable cases the use of the Plummer bag is advisable. Rarely, as in some cases of long-standing cardiospasm with megaesophagus, some type of plastic surgery of the cardia is indicated.

Benign stricture. Stricture of the esophagus may be congenital, the result of lye burn or the result of an inflammatory process. Diagnosis and treatment by esophagoscopy and bouginage are indicated. In any event, carcinoma must be ruled out, since it occasionally develops at the site of congenital or lye stricture (Benedict²⁴).

Esophagitis. Some physicians seem surprised when a diagnosis of esophagitis is proposed, but when one looks at the esophageal mucosa through the esophagoscope and finds it red and edematous, sometimes with exudate and mucosal proliferation, there can be no doubt of the existence of an inflammatory process. Such a diagnosis is suggested by substernal pain aggravated by swallowing. Hematemesis is not uncommon. The diagnosis is made only by esophagoscopy. Sometimes the process is so proliferative as to be confused with carcinoma; in such cases, a biopsy will establish the diagnosis, and suitable treatment can be instituted.

Peptic ulcer. Benign ulcers of the esophagus are rare. They occur at the lower end, and cause symptoms similar to gastric or duodenal ulcer. Unless there is a congenitally short esophagus or aberrant gastric mucosa, the term "peptic" is a misnomer. Esophageal ulcer may occur in association with gastric or duodenal ulcers, or with esophagitis, and the process may go on to stenosis (Jackson,²⁵ Benedict and Daland,²⁶ Klein and Hochbaum²⁷). Esophagoscopy is indicated for diagnosis and treatment.

Foreign body in the esophagus is usually recognized by the history and x-ray examination. Unless the foreign body passes quickly into the stomach, esophagoscopy is indicated to remove it. Because of the danger of perforation, blind bouginage for the purpose of forcing the foreign body into the stomach is to be severely condemned. Pushing the foreign body into the stomach at esophagoscopy is also to be deplored, for it is very rare indeed that a foreign body in the esophagus cannot be safely removed through the mouth. Most foreign bodies that have reached the stomach go through the pylorus and proceed through the intestinal tract

without undue delay. Sometimes, however, large objects fail to pass the pylorus, and certain long and sharp objects may encounter difficulty in following the turns of the intestine. Such foreign bodies may be removed by open-tube gastroscopy or by the use of Tucker's²⁸ sheathed flexible gastroscopic forceps under biplane fluoroscopic guidance. If perforation of the esophagus occurs either as a result of the character of the foreign body or as a result of instrumentation, radical surgical drainage is indicated to prevent mediastinal abscess.

Varices. Esophageal varices are now commonly recognized by x-ray examination (Schatzki²⁹). Since fatal hemorrhage is a frequent occurrence in patients with extensive varices, and since no surgical approach has been successful, injection of sclerosing solutions into the veins through the esophagoscope has been performed by Crafoord and Frenckner³⁰ and by Walters, Moersch and McKinnon.³¹ I have recently treated a patient in this manner.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27141

PRESENTATION OF CASE

First Admission. A fifty-one-year-old woman entered the hospital complaining of abdominal pain.

The patient had a story of generalized abdominal pain localizing in the right lower quadrant, anorexia, constipation and vomiting of two days' duration. The abdomen was tympanitic and quiet, with spasm and marked tenderness in the right lower quadrant; the white-cell count was 11,700, the temperature 100°F. A diagnosis of acute appendicitis was made, and at operation about 100 cc. of thin fecal pus was found in the peritoneal cavity, together with two free-lying fecaliths, the whole contained in a cavity whose lower medial wall was composed of small bowel bound together by thin inflammatory film. The appendix was retrocecal and had a large perforation near its base that had almost transected it. It was resected, and a chromic tie placed about the base; the wound was closed around two cigarette wicks. Postoperatively the patient was given sulfapyridine and two 500-cc. blood transfusions. Purulent material drained from the wound for nine days, and she ran a temperature until the nineteenth postoperative day, generally spiking to 101°F., but occasionally to 102. The white-cell count was 14,000 on the twelfth day, but rapidly became normal. The patient was discharged twenty-four days after admission.

Final Admission (five months later). One month after discharge the patient came to the Out Patient Department for a routine follow-up with the single complaint of gas pains two days previously; physical examination was negative. She was well until six days before admission, when a non-radiating epigastric soreness developed, accompanied by anorexia and nausea. This dull pain soon became generalized and finally localized in the hypogastrium, at which time she suffered from urinary incontinence and burning. The pain continued for two days and was associated with constipation; she took castor oil, which resulted in several bowel movements and great relief. At the time of observation, pain had been absent for two days, although anorexia had persisted. The tem-

perature was found to be 103°F., so that immediate admission was advised.

On examination the patient was well developed and well nourished and in no acute distress. Examination of the heart and lungs was negative; the blood pressure was 115 systolic, 80 diastolic. The abdomen was not tender, and peristalsis was very active. There was slight right costovertebral tenderness. On pelvic and rectal examinations one examiner felt an ill-defined, irregular mass in the right vault.

The temperature was 103°F., the pulse 100, and the respirations 30.

The urine was normal. The blood showed a red-cell count of 4,000,000 with a hemoglobin of 75 per cent, and a white-cell count of 19,900 with 87 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 19 mg., the protein 6.7 gm. per 100 cc., the serum van den Bergh slightly above normal (biphasic) and the chlorides 955 milliequiv. per liter. Agglutination reactions for typhoid and paratyphoid bacilli and *Brucella abortus* were negative.

A flat abdominal x-ray film showed no dilated loops. There was a moderate amount of gas in the right half of the colon, and a small quantity of gas in the small bowel. A Graham test showed a segment of bowel, apparently the small intestine, unusually high and in front of the liver. A faint shadow of the gall bladder was seen within the shadow of the liver, with a round area of decreased density near the fundus consistent with a cholesterol stone. An x-ray film of the chest showed the diaphragm to be high on both sides, motion being slightly less on the right. The lung fields were clear, and the heart was transverse in position, but not definitely enlarged.

On the third hospital day there were diminished resonance and fremitus at the right lung base, with no rales, but many loud rhonchi and a definite friction rub over the area; the right diaphragm moved fairly well. Slight spasm was present in the right upper quadrant of the abdomen, the liver was 1 cm. below the costal margin and there was right costovertebral tenderness. Five days later the patient was much worse, her eyes were sunken, and she was sweating profusely but complained only of an occasional pleuritic pain in the right posterior chest. The abdomen was tender below the costal margin in the anterior axillary line, and there was some muscle resistance there, but no true spasm. She began to suffer from chills, and the scleras became slightly icteric; pain was referred to the right scapular region. The next day there was tenderness on percussion over the right costal margin; the right diaphragm was

higher than the left and moved hardly at all; coarse rales were present at both lung bases, more pronounced on the right. The white-cell count was 34,000, the hemoglobin 60 per cent.

An operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. HENRY H. FAXON: Perhaps we had best start by looking at the x-ray films.

DR. AUBREY O. HAMPTON: This plain film of the abdomen shows gas in the right colon.

DR. FAXON: Is it necessarily in the colon?

DR. HAMPTON: Yes. That is the cecum, and this, the hepatic flexure; there is not much gas in the small bowel. However, I do not believe there is enough gas anywhere to be of much significance. It does not indicate obstruction, so far as I can tell. The gall bladder did not concentrate the Graham dye normally, but just enough to show a large nonopaque stone.

DR. FAXON: In the record it says, "A Graham test showed a segment of bowel, apparently the small intestine, unusually high and in front of the liver."

DR. HAMPTON: I do not get that impression. These bubbles could be in the colon. I do not consider the condition abnormal.

DR. FAXON: And the shadow that you see there is almost certainly a gallstone?

DR. HAMPTON: Yes. It maintains its relation with a faint shadow of the gall bladder. I think we can be fairly certain that there is a stone.

DR. FAXON: When I first read the report, I considered the possibility whether the shadow described in the region of the liver could be an abscess cavity in the liver rather than a gall bladder with stone.

DR. HAMPTON: I do not believe that it could.

DR. FAXON: We have a fifty-one-year-old woman with the classic signs of acute infection, which we can readily localize within certain limits. In cases in which a liver abscess or a subphrenic abscess is suspected, the differential diagnosis is often further confused by the presence of chest signs or symptoms that make it difficult to decide whether the process is above or below the diaphragm. In this case, from the past history, from the earlier x-ray studies and from the chest examination, we can safely conclude that the infectious process is not in the chest itself. The diaphragm was limited and high, and the patient had some pleuritic pain, but these findings could certainly be accounted for by irritation below the diaphragm.

Is there anything to suggest that the infectious process might be in the kidney? We have the finding of costovertebral tenderness on one occa-

sion, and also a note of burning and frequency of urination. I think it is worth pointing out that one should not jump to the conclusion that costovertebral tenderness is of necessity due to disease of the kidney. With a subphrenic abscess one of the most typical findings is tenderness in that region, more especially brought out by pressure over the twelfth rib than by pressure in the angle itself. Inasmuch as later in the story the urine was negative and the nonprotein nitrogen normal, it seems to me that we can rule out the kidney as the site of this infection.

What part might the intestinal tract have played in the symptomatology? The crampy pain, the hyperactive peristalsis on examination and the relief from discomfort with bowel movements all suggest the possibility of obstruction. However, obstruction would not account for the high temperature and persistently high white-cell count. I think it is more than possible that in the walling off of the original inflammatory process the patient may have developed adhesions between loops of small intestine that gave rise to a certain degree of subacute obstruction accounting for the early symptoms one month after her discharge from the hospital; these adhesions may have been a contributing but relatively unimportant factor when she came in at this admission.

That brings us to the gall bladder. We have the story of right-upper-quadrant pain, with radiation to the right posterior chest. We have jaundice as the disease progressed, and furthermore we have the perfectly definite finding by Graham test of a stone in the gall bladder. Can the whole picture be accounted for on the basis of cholecystitis and cholelithiasis? It seems to me that with such a high white-cell count and temperature, there would have been more striking physical signs in the gall-bladder region if the pathologic process had been confined to that area. One of the early signs was tenderness in the costovertebral region rather than in the anterior part of the abdomen, and as the story progresses the tenderness and spasm were almost always well lateral and posterior rather than in the region of the gall bladder itself. I do not believe, therefore, although the patient had a definite stone, that cholecystitis and cholelithiasis were the main factors in this case.

With the antecedent story of ruptured appendix, we come down to a differential diagnosis between subphrenic abscess and liver abscess secondary to pylephlebitis. It may seem to be of somewhat academic interest to try to make a distinction between these two conditions, but as a matter of fact it is of extreme practical importance to the surgeon if he is going to drain the area to know which of the two situations exists. In favor of

liver abscess we have as the most significant thing about the first entry with its operation for her ruptured appendix the fact that the temperature, instead of returning to normal, persisted around 101 and 102°F. for a period of over two weeks. Before operation on the second admission, the patient had chills and jaundice; the diaphragm, which was elevated but not fixed at first, later became almost fixed, and the liver was said to be enlarged. It might be of interest to pause a moment and consider the incidence of chills in relation to pyelphlebitis in association with appendicitis. Of the cases of ruptured appendices in this hospital, approximately 10 per cent gave a history of chills prior to operation. Only 10 per cent of these, however, went on to develop pyelphlebitis. On the other hand, of the patients who are known to have had pyelphlebitis, almost all at some time in the course of the disease complained of chills. The incidence of pyelphlebitis and liver abscess with acute appendicitis is approximately 0.5 per cent. So much for the possibility of liver abscess.

What evidence have we to endorse a subphrenic abscess as the cause of this patient's symptoms? Again we have the history of ruptured appendix, on the first admission, with thin pus and two fecaliths free in the peritoneal cavity. The thin pus could have been aspirated into the subdiaphragmatic region, since the pressure in the upper abdomen with quiet respirations is less than that in the lower portion. If there were two fecaliths, there might have been a third that could have served as a focus for persistent infection and possible abscess formation. The incidence of subphrenic abscess with acute appendicitis is about twice that of pyelphlebitis. The high diaphragm, which is a finding that is almost always present with a subphrenic abscess, is present in about half the cases of liver abscess. However, the motion of the diaphragm is far more apt to be restricted or absent with a subphrenic abscess than with a liver abscess. The objection might be raised in considering these two diagnoses that, because of the long interval between the inciting appendectomy with drainage and the subsequent development of the condition that the patient showed, they could be excluded. It was of interest to me in reviewing the cases of subphrenic abscess in this hospital since 1900, however, to find that almost 10 per cent of the patients gave a story of over three months from the time of the inciting cause to the time of the drainage of the abscess. It is only fair to say that many of the long delayed cases were in the early years of that period and far fewer in the later years.

From the history as given here, I should think that we must explain in some way the change in the picture from apparent health to illness that occurred six days prior to entry. Had it been a subphrenic abscess from the start, I do not believe there would have been so abrupt and sudden an onset six days before the patient came in the second time. The only way that I can rationalize that short story on the basis of either a liver or subphrenic abscess is to assume that the collection of pus that had developed secondary to the first operation ruptured or leaked six days prior to the time that she came in. The fact that there were so few signs in the chest at the time of entry is against a long-standing subphrenic abscess. This is not inconsistent with long-standing liver abscess, and I believe that what happened in this case was that the patient had a gangrenous appendix, developing a subclinical pyelphlebitis with a residual liver abscess, and that the abscess had smoldered along for five months and finally came to the surface of the liver, either to leak or to cause further irritation in one of the subphrenic spaces.

My diagnosis is liver abscess, with secondary subphrenic abscess and the incidental findings of cholelithiasis and pleuritis.

DR. OLIVER COPE: This patient's second admission came when I was on service. The history is a bit misleading, although it is the history that she gave. She was a very uncomplaining woman, and it was only on further questioning after the preliminary studies had been made that we found out what had happened before the onset of the immediate symptoms bringing her to the hospital. It was obvious that she had never been well from the time of the first admission and that her difficulties were due to a complication after appendicitis, even though it was five months from the time of the ruptured appendix. We argued, like Dr. Faxon, that it must be either liver abscess or subphrenic abscess. There were not sufficient signs immediately, but when the temperature began spiking and the van den Bergh became positive (the jaundice was not really noticeable clinically), we suspected that it was a liver abscess. Dr. Howard Ulfelder operated on the patient, and I scrubbed up with him. He made a diagnosis of liver abscess. I was not sure it was not subphrenic abscess in view of the positive signs that she showed. It turned out that it was quite a large liver abscess. Dr. Ulfelder resected the twelfth rib on the right side and then inserted a needle in two or three places. Finally pus was found. There was nearly a centimeter of uninvoluted liver protecting the subphrenic space, but in spite of that there was considerable edema and inflamma-

tion on the undersurface of the diaphragm, so that there was really an incipient subdiaphragmatic abscess. This inflammation accounted for the chest signs. We suspected that there might be other abscesses, even though the abscess cavity was at least 10 cm. in diameter.

The postoperative course was stormy. The infection was progressively severe and overwhelming; the patient died in spite of chemotherapy nine days after drainage of the abscess. The chart is interesting. During the week she was in the hospital before operation the temperature climbed to 103°F. After the operation the temperature dropped to normal for several days, but clinically the patient did not improve so much as the drop in temperature indicated. The pulse was 100 to 120, and there was a terminal abrupt rise. We suspected that we had drained only one of several abscesses within the liver.

CLINICAL DIAGNOSES

Liver abscess.

Subdiaphragmatic abscess.

DR. FAXON'S DIAGNOSES

Liver abscess, with secondary subdiaphragmatic abscess.

Cholelithiasis.

Pleuritis.

ANATOMICAL DIAGNOSES

Multiple abscesses of the liver.

Peritonitis, acute fibrinopurulent.

Icterus.

Cholelithiasis.

Leiomyoma of uterus.

Surgical wounds: appendectomy; drainage of liver abscess.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The autopsy showed numerous other abscesses. There were two large ones and a very considerable number of abscesses 0.5 to 1 cm. in size. It would obviously have been impossible to drain the major proportion of them. The autopsy was limited to the abdomen, so that I cannot say whether there was a pleuritis or not. The portal vein was dissected with care, and no evidence of thrombosis could be made out. A rather unexpected finding at autopsy was a severe general peritonitis. This was evidently of some duration, since most of the pus was in well-isolated pockets and there was very little fluid free in the peritoneal cavity. Some of the localized pockets were of considerable size, including one 6 cm. in diameter just lateral to the cecum. At what time peritonitis developed I do not believe we can say—presumably very close to the time the abscess

was drained but whether before or after I do not know.

DR. COPE: The general peritonitis was a surprise to us. We did not clinically appreciate it. Whether it had any relation to the obstipation and the catharsis that the patient had had before coming in we do not know. Another possible source of the peritonitis is that, since we obviously opened into a clear fascial plane above and behind the liver, we opened new pathways to infection that had not existed at the time of the ruptured appendix. Do Dr. Mallory and Dr. Faxon agree that we were right in assuming that the liver abscesses were the result of portal-vein infection?

DR. MALLORY: I think there is very little doubt that that must have been the pathway of infection. It was presumably a matter of metastasis of a few organisms rather than an ascending thrombophlebitis.

To conclude: a gallstone was present. We found no organic obstruction of the bowel. The only other finding was a moderately large fibroid of the uterus, which was evidently the mass that one examiner found on pelvic examination.

DR. FAXON: May I ask Dr. Hampton if there is any way of showing a cavity of that size in the liver by x-ray?

DR. HAMPTON: Yes, when it is filled with gas or when Thorotrast is given.

CASE 27142

PRESENTATION OF CASE

First Admission. A fifty-five-year-old Swedish-American shovel polisher entered the hospital for study.

While working one hot day nine months before admission, the patient felt drowsy and stated that he was unable to sweat; several of his colleagues were similarly affected. Since that time he had been troubled with a nocturia of twice a night, and for the next two months his skin was dry and never perspired. Two months before entry, a pleuritic pain developed over the third and fourth ribs in the right anterior axillary line, accompanied by a slight cough with a small amount of white sputum. The following day his physician recorded an elevated temperature and a pulse of 100, with a few rales at the right apex. Strapping the chest eased the pain, which disappeared in three or four days. A few days later, the patient caught cold, and again there was cough with slight sputum, but no pain; these symptoms continued for a month, and he was weak and slightly dyspneic on exertion and was forced to give up working. Three weeks before admission his physician noted occasional rales and wheezing in both lungs.

The sputum was said to have been negative for tubercle bacilli, and an x-ray film of the chest showed clear apices and no pleural fluid, but a soft shadow and small calcified nodules in both lung roots. There was no gross consolidation or cavitation. Four days prior to entry a "sore spot" developed below the left costal margin, and pressure over this point gave pain in the right shoulder. In a period of half an hour the soreness gradually shifted across the epigastrium to below the right costal margin and from there to the ribs above the costovertebral angle. It was aggravated by deep breathing, when pain was also noticed in the right shoulder. Strapping the chest again gave relief. His physician stated that the patient's skin had grown darker during the previous six months. He had lost 15 pounds in weight.

The patient had had gonorrhea at twenty-eight, and fifteen years before entry "rheumatism" for ten weeks, characterized by pain without swelling, first in the knees, then "all over the body."

On examination the patient was a rather poorly nourished red-haired man with freckled pigmentation of the skin, but not of the mucous membranes. The eyes were prominent, with widened palpebral fissures and lid-lag; the thyroid gland was not enlarged. The nasopharynx was reddened. The chest was somewhat barrel-shaped, and tenderness was present over the lateral edge of the right trapezius muscle in the neck. Percussion posteriorly revealed a 4-cm. excursion of the diaphragm on the left, with none on the right. Posteriorly dullness was present to the ninth rib on the left, and to the seventh rib rising into the axilla on the right; anteriorly the upper border of dullness reached the fourth rib on the right. On auscultation the left lung was clear, but on the right there were diminished breath sounds and vocal resonance over the area of dullness, with a few coarse rales immediately above it. The heart was normal; the blood pressure was 135 systolic, 95 diastolic. The liver was palpable four finger-breadths below the costal margin in the mid-clavicular line. There was a slight tremor of the hands. Rectal examination was negative.

The temperature was 97°F., the pulse 90, and the respirations 20.

The urine showed a ++++ sugar reaction. Examination of the blood showed a red-cell count of 5,200,000 with a hemoglobin of 99 per cent, and a white-cell count of 8500 with a normal differential. The fasting blood sugar ranged from 138 to 185 mg. per 100 cc. A bromsulphalein test was normal, and a formol-gel test showed minimal gelling in twenty-four hours. The blood Hinton reaction was negative. Examination of the spu-

rum and stools was negative. Determinations of the basal metabolic rate gave readings of +39 and +33 per cent. A biopsy of the skin was normal.

An x-ray film of the chest showed the right diaphragm to be elevated, with only a very small respiratory excursion. There were several plate-like foci of atelectasis, and one of these areas arose from a triangular shadow that lay close to the pleural surface. There was no definite evidence of fluid, and the lung fields were otherwise not remarkable. The size of the heart was at the upper limits of normal, and there was calcification of the aorta. A week later the right diaphragm was normal in position, with normal respiratory motion. No fluid was visible, and the lung field appeared normal.

A flat film of the upper abdomen showed the lower border of the liver to be slightly lower than usual, particularly on the left side. The spleen was not enlarged. There were several areas of calcification in the region of the lower edge of the liver on the right side, as well as an area of calcification behind the stomach on the left. Gallstones were thought to be the most probable explanation for the calcified areas on the right side. There was no evidence of varices in the esophagus.

The patient was iodized, and the diabetes brought under control with insulin. A subtotal thyroidectomy for hyperthyroidism was performed three weeks after admission. He was discharged one week later on a diabetic diet with no insulin.

Second Admission (eight months later). The patient was seen three weeks after discharge and had improved very satisfactorily. His appetite was good, and he had gained in weight and strength. There was no tremor, nervousness, palpitation, excessive thirst or frequency, though a nocturia of once a night was still present. A moderate edema about both eyes was noted, and the right eye was still a bit prominent, without lid-lag. The heart was slow and regular, the blood pressure 140 systolic, 108 diastolic, and the basal metabolism rate -2 per cent. Two months later, the findings were the same, but the urine gave an orange sugar reaction, and the blood sugar was 210 mg. per 100 cc., so that insulin therapy was instituted. Four months before admission, the patient began to suffer from fatigue; his legs felt tired and heavy, with a "numb feeling" at the instep of the right foot. In addition, he noticed transient spells of "wooziness," with a staggering gait lasting but a few seconds. Six weeks before entry, he noticed that his skin was becoming dry and scaly. At the time of admission, he volunteered in a slow, deep, husky voice that he worked and thought more slowly than before, and complained of constipation and a dislike of cold weather. It ap-

peared that from the time of discharge until one month before admission the patient had suffered from cramps in his calves and forearms when they were exercised. He had gained 32 pounds since operation.

On examination the skin was dry, rough and scaly, and had a slight yellowish tinge. The heart and lungs were normal, the blood pressure 140 systolic, 90 diastolic. The liver was palpable three fingerbreadths below the costal margin.

The temperature was 97.8°F., the pulse 67, and the respirations 18.

The fasting blood sugar varied from 112 to 296 mg. per 100 cc.; the nonprotein nitrogen of the blood serum was 21 mg. per 100 cc., the carbon dioxide combining power 33 milliequiv. per liter, and the total cholesterol 150 mg. per 100 cc. Brom-sulfalein and formol-gel tests were negative. A glucose-insulin tolerance test showed slight resistance to insulin.

The basal metabolism rate varied from -14 to -30 per cent. X-ray examination of the chest showed the heart size to be within the upper limits of normal. The aorta was calcified, but not dilated, and the lung fields showed slight increase in the lung markings.

The patient was discharged two weeks after admission on thyroid, a diabetic diet and 20 units of protamine insulin daily.

Final Admission (one year later). The patient was followed in the Out Patient Department and remained well, although the dosage of thyroid had to be increased to combat the symptoms of myxedema. Suddenly four days before admission general malaise, headache, muscle pains and backache developed, with a slight cough and a temperature of 102°F. Two days later he became weak, drowsy and difficult to manage; he refused to eat, and his cough increased. At the time of admission it was found that he had not taken insulin for at least a month.

On examination the patient was drowsy, uncooperative and coughed frequently. There was facial telangiectasia, with cyanosis and a curious slate-colored pigmentation of the dry skin. The nasopharynx was reddened and edematous. Many rales were heard throughout the chest, being most marked over the right lower lobe, but there was no evidence of consolidation. The heart was normal, the blood pressure 100 systolic, 64 diastolic. The liver was palpable 4 cm. below the costal margin. The reflexes were slow and deliberate, but equal.

The temperature was normal, the pulse 95, and the respirations 20.

The urine showed a ++++ test for albumin, an olive sugar reaction and a ++ test for acetone. Ex-

amination of the blood showed a red-cell count of 3,750,000 with a hemoglobin of 11 gm. (photoelectric-cell technic), and a white-cell count of 13,100 with 82 per cent polymorphonuclears. The blood sugar was 392 mg. per 100 cc., and the carbon dioxide combining power 21.9 milliequiv. and the total base 154.5 milliequiv. per liter; the pH was 7.36. The nonprotein nitrogen of the blood serum was 35 mg. per 100 cc.

The day after admission, definite signs of consolidation had developed in the right lower lobe, with scattered areas in the left lung. The temperature had risen to 103°F., the pulse to 130 and the respirations to 30. Chemotherapy was instituted, but the patient failed rapidly and died on the fourth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. JOHN R. GRAHAM: This man was a shovel polisher. It is a trade of which I have never heard, and whether it offers an occupational hazard I do not know. So far as I can make out, the past history is inconsequent. At the first admission it was evident that the patient had a protean collection of symptoms involving several systems of the body. The increased frequency of urination fits with the presence of sugar in the urine, and the high blood-sugar level serves to establish a diagnosis of diabetes. Secondly, the eye signs, the rapid pulse rate and the elevated metabolic rate point to a diagnosis of hyperthyroidism. I am sorry that the record does not include a figure for the basal metabolic rate after iodine had been administered, which would have been conclusive evidence of this diagnosis, but since a thyroidectomy was performed I think we may assume that the response to iodine was what might have been expected. From the physical examination we learn that the liver edge was palpable four fingerbreadths below the costal margin, and with such a finding I believe we are safe in assuming that the liver was enlarged. In this connection it is interesting to note that a biopsy of the skin was performed, and despite the statement of the patient's physician that his skin had become darker no abnormal pigment was observed. Finally we have a puzzling group of signs and symptoms in the chest. One wonders if the dyspnea was due to the pulmonary process or to the hyperthyroidism. I should assume that the calcified nodules near the lung root meant old tuberculosis. The sign at the right base might have been due to a high fixed diaphragm, with atelectasis or a small collection of fluid, or to a consolidating process of the right lower lobe. The evidence of the chart and the normal white-cell count

are against any very acute infection. The patient had had two or three episodes, each associated with pleural pain, increased dyspnea and sufficient disability to lead him to stop working. It seems to me that a series of pulmonary infarcts was the most likely explanation of what was going on in the chest, and the description of the x-ray findings was found consistent with this diagnosis. After operation it is evident that the symptoms of hyperthyroidism definitely regressed. Moreover it is interesting that despite the removal of the thyroid gland the diabetes apparently progressed, since insulin became necessary. The numbness complained of in the right foot may have been evidence of diabetic neuritis. At the second entry, it is evident that myxedema had developed, and it seems probable that this was secondary to the preceding thyroidectomy. The liver situation had apparently not changed significantly.

Four days before his final admission, the patient had symptoms that sound like an acute respiratory infection rather than infarct, which could hardly explain the headache, muscle pains and backache. I have little doubt that it was pneumonia. The diabetes was certainly no better. It is hard to say whether it had progressed or not. The patient seems to have been in mild acidosis. We have the added information of slate-colored pigmentation to the skin.

In trying to put this whole picture together, I find that it is hard to make all the symptoms and signs conform to one picture. There seems to be a fundamental triad of symptoms that cannot be neglected, namely, diabetes, enlargement of the liver and slate-colored pigmentation of the skin. Hemochromatosis seems to be the only thing to explain these symptoms in one patient. I have never heard of hyperthyroidism with hemochromatosis, and I can only regard this as a coincidence. We know that, in hemochromatosis, primary carcinoma of the liver is a complication in not a few cases, but I see no particular reason why we should make this diagnosis in the present case. My primary diagnosis is hemochromatosis, with pigmentation of the skin and viscera, cirrhosis of the liver and cirrhosis of the pancreas; additional diagnoses are myxedema secondary to operation, gallstones, deep phlebitis in the legs, an old process in the lungs, perhaps due to infarcts, probably some arteriosclerosis on a diabetic basis, a terminal pneumonia and diabetic acidosis.

DR. EUGENE SULLIVAN: There are one or two points worth mentioning about the case. I sent this patient in at the second admission. At that time he had spent four hours in the Out Patient Department, which is well heated ordinarily, yet he still had his overcoat on. It took about five

minutes to get a deep husky answer to any question. It is of some interest that he had been followed sporadically in the medical clinic during the preceding eight months without the detection of definite signs of myxedema. When he arrived on the wards the basal metabolic rate was recorded as low as -30 per cent. He had a well-developed myxedema. He was admitted with the added diagnosis of hemochromatosis, largely because I had the advantage of seeing a pathological report neatly tucked into the record of the first admission. Apparently not much attention had been paid to it, but there existed a careful description of hemochromatosis involving the thyroid gland. At the time I pondered whether the myxedema was partly on the basis of surgical ablation, and partly due to involvement of the remaining epithelial cells of the thyroid gland with the pigment deposit. However, most people believe that hemochromatosis affects functionally only the pancreas and the liver. After the patient arrived for his last admission I saw him in the Emergency Ward. He was sent in as a probable case of diabetic coma. It was obvious that it was not diabetic coma. He was cyanotic and mildly acidotic. He had only an olive sugar test in the urine and was a very ill man. He was so ill that although we thought he had a pneumonic infection, we were hesitant to give chemotherapy because we thought he could not stand anything at the moment except oxygen and warmth. We gave him small amounts of insulin—20 units all told. We discovered that he had taken no insulin during the previous four weeks. We marveled how he had been able to get through a whole month without insulin, and moreover to contract pneumonia, without going into diabetic coma. Several possible explanations were considered. First, a myxedema due to insufficient thyroid medication might have affected the diabetes. Secondly, regarding cirrhosis of the liver, we know that people with diabetes who develop cirrhosis may get over their diabetes clinically. Thirdly, we considered the possible effects of hemochromatosis involving the pituitary gland. Here was pigment deposit in the pancreas producing the picture of diabetes. Would hemochromatosis later involving the epithelial cells of the pituitary gland remove its diabetogenic function? There was no way of settling these points, but they made nice subjects for discussion.

CLINICAL DIAGNOSES

Hemochromatosis.

Pneumonia.

Diabetes.

Myxedema.

DR. GRAHAM'S DIAGNOSES

Hemochromatosis, with skin pigmentation and cirrhosis of liver and pancreas.
 Myxedema, postoperative.
 Diabetes, with acidosis.
 Gallstones.
 Pulmonary infarcts, old.
 Deep phlebitis of legs.
 Arteriosclerosis?
 Pneumonia, terminal.

ANATOMICAL DIAGNOSES

Hemochromatosis, involving liver, pancreas, thyroid gland and lymph nodes.
 Myxedema, postoperative.
 Bronchopneumonia, confluent.
 Pleuritis, healed fibrous.
 Icterus, slight.
 Telangiectasia of face.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: I must confess to having withheld some information from Dr. Graham. At the time of thyroidectomy we did find very large amounts of hemosiderin in the stroma of the thyroid gland—so much, in fact, that we made a diagnosis of hemochromatosis. Otherwise the histologic appearance of the thyroid gland was

consistent with a true hyperthyroidism and iodine involution.

At the time of autopsy we found a considerably enlarged, very finely granular and quite tough liver, which was of an abnormal red-brown color. The lymph nodes at the hilus of the liver were deep brown, the pancreas very distinctly brown; so that it was quite easy to make a gross diagnosis of hemochromatosis. Sections of all these organs dropped in a solution of potassium ferrocyanide and hydrochloric acid turned intense blue. Sections of the various endocrine glands were put through to see how extensive the iron deposits might be. The condition in the remaining part of the thyroid gland was essentially the same as at the time of operation. There was a small amount of pigment in the adrenal glands, virtually none in the pituitary gland. The pancreas showed a lot of pigmentation, but much more in the parenchymal cells than in the islet cells. We had again no luck in demonstrating iron in the skin, probably because of poor selection of the specimen for examination.

The mechanism of death was an extensive bronchopneumonia, and I am afraid we were so impressed with the pneumonia that we forgot to look for the scars of the infarcts, which the patient very well may have had. An ordinary routine examination of the lungs post mortem would certainly not rule out healed infarct.

ADULTERATED SULFATHIAZOLE TABLETS

FOR some unexplained reason two or more lots of 0.5 gm (77-gr.) sulfathiazole tablets released by the Winthrop Chemical Company, New York City, in December, 1940, contain a certain number of tablets that are composed, either in whole or in part, of phenobarbital. Practically all the bottles in these lots have been reclaimed from distributing houses, retail druggists and hospitals by representatives of the Winthrop Chemical Company and by inspectors of the United States Food and Drug Administration, but it seems likely that some are still in the hands of druggists, physicians and patients. The impure or suspicious lots are designated "MP," stamped in red ink on the up-

per right hand corner of the label on the bottle, the two known to be adulterated are labeled "MP 029" and "MP 118" respectively.

Although the administration of the adulterated tablets produces severe narcosis, practically all such patients have eventually recovered, and the chief danger lies in their use in cases of pneumonia or of other infectious diseases in which the patients are already gravely ill.

Several nonfatal cases have been reported in the vicinity of Boston, and any physician in New England, with the exception of those in the western half of Connecticut, who notes an unexplained and rapid loss of consciousness in a patient following the ingestion of a 0.5 gm (77 gr.) tablet of sulfathiazole should immediately report the fact to Inspector C. C. Sullivan of the United States Food and Drug Administration, Federal Security Agency, 408 Atlantic Avenue, Boston (Hancock 8890).

JOHN GILLIES PRIESTLEY

THE *British Medical Journal* for February 22 brings the unhappy news of the death of John Gillies Priestley on February 9. Educated at Eton and later at Christ Church, Oxford, Priestley, at the turn of the century, came under the influence of John Scott Haldane, whose friendship and early guidance determined his future career. He joined Haldane in a series of memorable investigations, the first fruit of which, issued in the *Journal of Physiology* in 1905 under the title, "The Regulation of the Lung-Ventilation," has become one of the classics of modern physiology, for it established the importance of carbon dioxide pressure in regulating the activity of the respiratory center. After this paper was published, Priestley proceeded to St. Bartholomew's Hospital in London to complete his medical qualifications, but shortly thereafter he fell ill and was obliged to spend several years in Switzerland.

Priestley was a keen sportsman and a man of unusual critical capacity. He had deep loyalties, and it was characteristic of him that, despite frail health, he volunteered immediately when World War I broke out, being commissioned on Septem-

ber 1, 1914, after which he served in France and Belgium. In 1915 he received the Military Cross and was also mentioned in official dispatches. Later in the same year he was called to England, where his training in the physiology of respiration was put to use in an important research on the aftereffects of war-gas poisoning. At the end of the war, he settled down at Oxford, and many students will recall his friendly interest and the warm hospitality of the Manor House, where he lived at March Baldon, near Oxford. They will also remember his unyielding insistence on the importance of objective evidence. He was joint author with Haldane of a laboratory text entitled *Human Physiology: A practical course*, and he joined Haldane in the preparation of the second edition of *Respiration*, a book based on the Silliman Lectures given at Yale University by Dr. Haldane.

Priestley rendered invaluable service to the Physiological Society in the preparation of a subject index of the first sixty volumes of the journal, and he succeeded his chief, Professor John Mellanby, as editor of *Physiological Abstracts*. He was responsible for the introduction of the international system of decimal classification of the scientific papers for the *Abstracts* and also for the papers in the *Journal of Physiology*. In the latter attempt to systematize the literature of physiology he had the enthusiastic support and co-operation of Sir Charles Sherrington. Priestley had broad interests in problems of general metabolism and of muscular exercise and in methods for determining cardiac output, a paper on the last subject having been published some two months prior to his death.

MEDICAL EPONYM

HEBERDEN'S NODES

The following is not a partial translated quotation, but represents the entire commentary made by William Heberden (1710-1801) on the nodes that perpetuate his name. It appears in his *Commentarii de Morborum Historia et Curatione* [*Commentaries on the History and Cure of Disease*] (Fourth edition, London, 1816).

What are those little hard knobs, about the size of a small pea, which are frequently seen on the fingers particularly a little below the top, near the joint. They have no connection with the gout, being found in persons who never had it; they continue for life and being hardly ever attended with pain, or disposed to become sores, are rather unsightly, than inconvenient, though they must be some little hindrance to the free use of the fingers.

A FATAL ABDOMINAL COMPLICATION IN PREGNANCY

A twenty-nine-year-old housewife consulted her family physician at the end of the third month her third pregnancy.

She had had no children, the first two pregnancies having resulted, respectively, in a premature labor at six months and an abortion at two months. She had been operated on five years previously for chronic appendicitis. The past history was otherwise noncontributory.

Physical examination at the time of her first visit was negative. The heart was not enlarged; there were no murmurs. The lungs were clear and resonant; there were no rales. The blood pressure was 120 systolic, 60 diastolic. Vaginal examination showed the uterus anterior and enlarged to a size consistent with the period of amenorrhea.

When the patient was about six months pregnant, she became severely ill, with nausea, vomiting and abdominal pain, the pregnancy previously having been normal. She was seen daily by her physician because of the nausea and vomiting, and since enemas gave no relief, she was eventually sent to the hospital, where she was seen by a surgeon in consultation. At his first visit he believed that there was no surgical condition, and ascribed the nausea and vomiting to toxemia of pregnancy. Two days later, however, fecal vomiting occurred and there was very definite tenderness in the right hypogastrium. A laparotomy was immediately performed and revealed a twisted loop of large intestine, which was necrotic. This piece of intestine came away on manipulation, and both ends of the large bowel were brought out through

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

opening in the abdominal wall. The patient died ten days after the onset of symptoms and forty eight hours after operation.

Comment. This case represents the importance of appreciating the significance of nausea, vomiting and abdominal pain during pregnancy. Had this woman not been pregnant, there is little doubt that the surgeon would have considered an exploratory laparotomy necessary because of a provisional diagnosis of intestinal obstruction. There is no evidence in the record of a temperature reading or a white-cell count when the surgeon first saw the patient. It is possible that there was no fever, but it is quite unlikely that there was no leukocytosis. Too frequently all symptoms during pregnancy are ill advisedly assumed to be due to pregnancy. A surgical abdomen is a surgical abdomen, whether it occurs in a man or a pregnant woman, and the sooner such abdomens are opened, even if an occasional one is opened unnecessarily, the sooner the number of deaths occurring from surgical complications will be reduced.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 6.

BERKSHIRE

Thursday, April 10, at 4 30 p.m., in the Bishop Memorial Building, Pittsfield. Pediatric Case Discussions. Instructor Clement A. Smith. Harry G. Mellen, *Chairman*.

BOSTON SOUTH (Fall River Section)

Tuesday, April 8, at 4 30 p.m., at the Union Hospital, Fall River. The Clinical Recognition of the Types of Jaundice and Recent Advances in Their Treatment. Instructor Franz Ingelfinger. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday, April 10, at 8 00 p.m., in the Library of the Franklin County Public Hospital, Greenfield. Obstetric Complications with Case Histories and Clinical Problems. Instructor John Rock. Halbert G. Stetson, *Chairman*.

HAMPTON

Wednesday, April 9, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and 8 00 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Head Colds and Complications. Instructor John R. Richardson. Alfonso A. Palermo, *Chairman*.

HAMPSHIRE

Thursday, April 10, at 4 15 p.m., in the Nurses Home of the Cooley Dickinson Hospital, North

ampton. Chemotherapy in the Treatment of Gonococcal Infection. Instructor P. N. Papas. Robert C. Byrne, *Chairman*.

WORCESTER

Tuesday, April 8, at 8 30 p.m., in the Nurses' Home of the Milford Hospital, Milford. Obstetric Complications with Case Histories and Clinical Problems. Instructor Roy J. Heffernan. Joseph Ashlins, *Chairman*.

WORCESTER NORTH

Friday, April 11, at 4 30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg. Infections of the Hands and Feet. Instructor Henry C. Marble. George P. Keaveny, *Chairman*.

DEATHS

BOOTH—ERNEST L. BOOTH, M.D., of East Boston, died March 24. He was in his fifty-eighth year.

Dr. Booth attended Boston Latin School and Harvard University and received his degree from Harvard Medical School in 1908. For more than thirty years he was a school physician in Boston, and had been physician for the East Boston plant of the General Electric Company and medical examiner for three insurance companies. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, two sons and two daughters survive him.

HOYT—EDWARD M. HOYT, M.D., of Georgetown, died March 28. He was in his eighty-fourth year.

Born in Wentworth, New Hampshire, he received his degree from Harvard Medical School in 1894. He spent a few months studying at the Rotunda Hospital in Dublin, Ireland, before starting practice in Georgetown.

Dr. Hoyt was a member of the Massachusetts Medical Society and the American Medical Association, having retired from active practice in 1936.

CORRESPONDENCE

REGIONAL FRACTURE COMMITTEES OF THE AMERICAN COLLEGE OF SURGEONS IN NEW ENGLAND

To the Editor. It might be of interest to readers of the *Journal* to know that the regional fracture committees of the American College of Surgeons in New England are endeavoring to improve the treatment of fractures.

Among the ninety-two of these regional fracture committees now operating in the United States and Canada, New England can boast of six—one for each state. Formed originally to call to the attention of surgeons, orthopedists and medical men the desirability of consolidating interest in the increasing number of fractures on the highways and their proper first aid and hospital treatment, the committees have gradually increased their scope.

The New England group is particularly fortunate in the educational field. Each regional chairman has a well organized committee, which holds a fracture symposium of its own at least once a year, the Boston teaching hospitals provide a one-day clinic for the full combined membership of the six regional committees once a year, and the New York, Philadelphia and New England groups hold a two-day clinic alternately in one of the three largest cities each year.

With three meetings a year, the members of these regional groups have an opportunity to keep informed and up to date on all accepted types of fracture treatment. These committees are active in all six states.

AUGUSTUS THORNDIKE, JR., M.D., *Secretary*,
Massachusetts Regional Fracture Committee.

319 Longwood Avenue,
Boston.

"FAITH HEALING"

To the Editor: Your issue of February, 1941, having included an article entitled, "Criminal Aspects of Faith Healing," by I. H. Rubenstein, and an editorial commenting on the article, may I request the publishing of this corrective letter?

Christian Science is not a "faith cure." Christian Science heals through an understanding of spiritual law. Faith is a component part of the healing work of Christian Science, but faith, which rests upon conviction, upon a demonstrable understanding of God's law, is far from a blind, though trusting, hope that prayer will be answered. Mary Baker Eddy writes, in her book, *Miscellaneous Writings*: "Christian Science is not a remedy of faith alone, but combines faith with understanding, through which we may touch the hem of His garment; and know that omnipotence has all power. 'I am the Lord, and there is none else, there is no God beside me'" (p. 97).

References made by the author of this article to decisions of courts in some jurisdictions seem to imply that Christian Science healing has been condemned by the courts. Findings favorable to Christian Science are not mentioned. Furthermore, practically all the decisions cited relate to occurrences of over a generation ago. They were made from the viewpoint of the then understanding of society as to what Christian Science is and what it does. As a rule society does not unanimously accept what appears to be an innovation. This is true in the arts and sciences, and in the practice of medicine.

In our tolerant and enlightened democracy, Christian Science has demonstrated its efficacy by its works. Consequently, a better understanding and recognition of its healing ministry is evidenced by the action of the citizens of our states in providing through legislative enactments that there may be treatment by prayer or spiritual means in the healing of the sick. So it is that whatever may have been the controversies before the courts in earlier times, it is clear that today healing by prayer has legal sanction and approval because the people wish it so.

The author of the article in question is apprehensive lest the "faith healer" will resort to material remedies in connection with his ministrations, that he will make physical diagnoses, prescribe and administer material remedies, and thus violate the medical-practice act. It need only be said that one who adheres strictly and in good faith to the methods of healing in Christian Science will not medically diagnose human ailments, nor will he use or administer material remedies in connection with treatment by prayer or spiritual means, for the simple and obvious reason that in so doing he would not be practicing the religion of Christian Science.

Your editorial expresses concern that those relying on prayer or spiritual means for healing may disregard quarantine and sanitary laws in cases of contagious and communicable disease. Christian Scientists carefully observe such laws and regulations. We have been told by our

leader, Mary Baker Eddy, to be law-abiding citizens. She has instructed us to "obey strictly the laws that be" (*Message to The Mother Church for 1901*, p. 34).

Mr. Rubenstein refers to "exploiting faith healing for commercial profit," and makes a distinction between treatment given in an office building and treatment given in the practitioner's own home or that of the patient or in a church edifice. If the "effectual fervent prayer" of a Christian Scientist is beneficial, can it be said that it is harmful or less beneficial if compensation is given therefor? Jesus, when sending forth his disciples under the injunction to preach the gospel and heal the sick, said, "The labourer is worthy of his hire." If the ministry in general in its redemptive work is entitled to compensation, and justly so, can it be said that Christian Scientists who devote their entire time to the practice of a religion that heals the sick, are less worthy? In her book, *The First Church of Christ, Scientist, and Miscellany*, Mrs. Eddy says: "Till Christian Scientists give all their time to spiritual things, live without eating, and obtain their money from a fish's mouth, they must earn it in order to help mankind with it. All systems of religion stand on this basis" (p. 216).

With respect to the point raised by the author relative to "criminal responsibility of parents" who do not supply medical care for their children, because of "a conscientious belief in faith healing," it will appear that the cases he has cited and his approach to the question must be considered and judged from the viewpoint of society at that time. The author refers to "necessary medical care." What is considered "necessary" in one age may not be so considered in another. The experience of mankind has demonstrated that the word "necessary," as applied to the healing of its ills, is not confined to "necessary medical care," but includes treatment by prayer or spiritual means, as countless of its beneficiaries can attest.

Speaking in a decision cited by the author (People v. Cole), regarding the construction of the statute under consideration in that case, Chief Judge Bartlett, of the Court of Appeals of New York, said, "I deny the power of the legislature to make it a crime to treat disease by prayer."

Many legislatures in our country have specifically provided that parents may have for their children the care and treatment of their choice. One notes an ever-increasing tendency in federal and state legislation to safeguard the interests of parent and child in permitting the remedial care of their own selection and in providing that a child is not to be considered as neglected who has "other remedial care."

Christian Scientists rely on prayer or spiritual means for the healing of the sick, without the use of material remedies. Christian Science is not a "faith cure" nor an emotional process, but is a restatement, in modern times, of the primitive Christian healing practiced by Jesus. In her famous textbook, *Science and Health with Key to the Scriptures*, Mrs. Eddy writes: "The physical healing of Christian Science results now, as in Jesus' time, from the operation of divine Principle, before which sin and disease lose their reality in human consciousness and disappear as naturally and as necessarily as darkness gives place to light and sin to reformation" (Pref. xi).

REPORT OF MEETING

NEW ENGLAND SOCIETY
OF PHYSICAL MEDICINE

At a regular meeting of the New England Society of Physical Medicine at the Hotel Kenmore on January 22, Dr Hallowell Davis discussed the Clinical Significance of the Electroencephalogram.

Dr Davis believes that the method is valuable for diagnosis but not for treatment. In contrast to the electrocardiogram the rate is faster and voltage very much less. The latter is one reason for the relatively late discovery, another being the irregularities of rate and amplitude, which were originally considered insignificant. The speaker briefly discussed various methods of placing the electrodes. Slides were then shown of the different types of waves. Normally there may be some variation in the height of the wave, but this is usually constant for each patient. There is a prominence of the ten cycle rhythm in the intermediate waves, there is more variation but there is a stable base line. In abnormal tracings the rates are grossly irregular, and the waves have characteristic shapes.

A motion picture was then shown demonstrating the maturation of the brain wave pattern with increasing age. At ten days there are practically no waves, at six months irregularities are characteristic, being slow, of wide amplitude and of random pattern, at five years there is more regularity, some faster components and the fundamental rhythm appears in runs. At seven years the fundamental rhythm becomes more prominent, is decreased or absent on opening the eyes, and varies with the state of sleep. Finally, the characteristic adult pattern was shown. The individuality of pattern is similar to that of handwriting, but the close resemblance of patterns in identical twins seems to indicate that it is an inborn characteristic. Brain waves are not exclusive with human beings for similar tracings may be found in animals of very low order.

Dr Davis discussed conditions that cause a variation in brain waves. The amplitude is decreased most surely by opening the eyes. Arithmetical problems may or may not cause a diminution depending on how sensitive the patient is about being put on the spot. When the patient goes to sleep, the waves become larger and slower, manifesting the same depression as other physiologic activities. Oxygen want acts by a similar mechanism as does a low blood sugar level such as that occurring in the insulin treatment of schizophrenia. Alcoholic intoxication causes surprisingly little depression in the deeper stages and there is a slow return to normal proportional to the alcoholic content of the blood. It increased intracranial pressure the pattern becomes slow, irregular and disorganized, no localization being possible when the increased pressure is generalized. In such cases multiple tracings are advantageous.

Among conditions that cause an increase in the pattern are convulsions, whether of Metrazol origin or from epilepsy. The possibility that the increased waves during Metrazol treatments may be of muscular origin has been ruled out in experimental animals by the use of curare. In epilepsy there are besides the characteristic waves during a seizure the telltale tracings between seizures. In the grand mal type of epilepsy, there is an increase in amplitude and rate with some slow components. The petit mal seizure is usually accompanied by the characteristic spike and wave pattern. The psychomotor attack results in variable tracings with a six per second rate. In conclusion, Dr Davis stated that the electroencephalogram is valuable

for localizing intracranial disease, detecting epilepsy and following up epileptic treatment.

The second speaker was Dr Robert Schwab, who recounted how the number of such studies at the Massachusetts General Hospital had increased from 20 per month in 1937 to 250 at the present. Dr Schwab stated that, besides the diagnosis of epilepsy and the localization of tumors, the method may be employed for recording other emanations such as those from the neuromuscular system. The speaker then discussed its use in the localization of tumors. Five hundred electroencephalographic studies have been carried out at the Massachusetts General Hospital and they are grouped as positive, uncertain and negative for tumor. Of those in the first group 40 of 45 cases have been verified and in the third group the results have been approximately 90 per cent correct. This compares favorably with the results obtained with myelography, and where both agree the results have been 100 per cent correct. From a practical standpoint it is well to be aware that the use of electrocautery in the operating room nullifies the electroencephalogram. It was also pointed out that by this method one is unable to differentiate subdural hematoma or brain abscess and tumors.

The third speaker was Mrs Pauline Davis, who has had considerable experience with this method in mental institutions. She has found that poor co-operation may be due to a real inability of the patient to concentrate, as manifested by the slow tracings in such patients. In an attempt to correlate the diagnosis with the brain wave pattern Mrs Davis divided the tracings into three groups according to their form and then looked up the diagnoses of these patients. It was found that the 244 schizophrenic patients fell into these three groups and that the type of schizophrenic corresponded well in the majority of cases. The patients in the first group with normal tracings were paranoid and usually stable on the ward; the second group revealed dysrhythmic waves and the patients were catatonic and unpredictable in their behavior; the third group had choppy patterns and the patients were also catatonic but stable although retarded, mute and unresponsive.

Occasionally some underlying disease was found to be responsible for the insanity. In this group in which the patients show organic damage Metrazol therapy is probably contraindicated for many show increased damage after treatment as recorded by the electroencephalogram. Even in those who show a good temporary response, there is usually some eventual damage, with failure of the brain to return to normal activity following therapy. It seems therefore that this is a good method for determining the status of the brain prior to treatment and for following the course of treatment.

During the discussion Dr Davis stated that the locus of origin for brain waves is well localized in the gray matter despite the physiologic interconnections of various parts of the brain. The pattern in hibernation it was stated would probably be slow, as in sleep. It is impossible to state whether this latter phenomenon is due to anoxia but Dr Davis believes that this is not the explanation. Refrigeration experiments at the McLean Hospital have been carried out but it has been found that the extreme shivering interferes too greatly with the results.

In discussing schizophrenics Dr John Romano pointed out that slow waves may be found in other problem patients. And although psychologists admit the heterogeneity of schizophrenics he considers it premature to believe that any correlation of types with brain waves is possible at present.

The so-called "frequency analyzer" may have some advantages, but it cannot record wave form, which is so important in epilepsy, for example. In answer to the question how long a record is necessary before epilepsy may be diagnosed or ruled out, it was stated that 90 per cent of positive clinical patients revealed some abnormality within ten minutes, or within three minutes during over-ventilation. Most of the other 10 per cent reveal characteristic tracings if several tests are carried out on successive days. It was pointed out that about 10 per cent of normal people with abnormal brain-wave patterns have moderately abnormal tracings, whereas none are so markedly pathologic as those among the frankly deranged. It was emphasized that a person who is clinically free of epilepsy may be able to pass on the trait genetically.

In the localization of deep tumors, the results have so far been more uncertain than in the more superficial ones. Differentiation between idiopathic epilepsy and the post-traumatic type may often be made by the generalized irregularities of the former, compared with the focal derangements in the latter. Mrs. Davis pointed out that the electroencephalogram in the depressed manic-depressive patient merely swings in his rare moments of manic activity toward the normal.

NOTICES

ANNOUNCEMENTS

DR. BERNARD APPEL announces the removal of his office from 483 Beacon Street, Boston, to 281 Ocean Street, Lynn.

DR. LOUIS E. WOLFSON announces the reopening of his office at 113 Bay State Road, Boston, for the resumption of his practice.

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Thiede, formerly concertmaster of the Cleveland Symphony Orchestra, every Thursday at 8:30 p.m. Those interested in becoming members should com-

municate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, April 15, at 12 m. Dr. Richard Chute will speak on "The Present-Day Treatment of Prostatism."

Physicians are cordially invited to attend.

TUFTS CHAPTER OF ALPHA OMEGA ALPHA

The Tufts Chapter of Alpha Omega Alpha will hold its annual lecture at Tufts College Medical School, Room 5, Thursday, April 10, at 4:15 p.m. Dr. Harold D. Chope will speak on "Public Health and National Defense."

All interested are cordially invited to attend.

TUFTS MEDICAL ALUMNI LECTURE

The annual alumni lecture of the Tufts College Medical School will be given at the medical school on Wednesday,

April 9, at 4 p.m. Dr. Sara M. Jordan, '21, will speak on "Gastrointestinal Diseases."

Physicians and medical students are cordially invited to attend.

HOSPITAL COUNCIL OF BOSTON

The annual meeting of the Hospital Council of Boston will be held at the Palmer Memorial Hospital, 195 Pilgrim Road, Boston, on Tuesday, April 15, at 12:30 p.m.

PROGRAM

Current Legislation. Dr. Henry M. Pollock.
Uniform Hospital Accounting. Mr. Frank E. Wing.
Convalescence and the Nursing Home Information Bureau. Miss Carrie M. Hall, R.N.

Members of the medical profession are cordially invited to attend. The charge for luncheon will be 75 cents. Reservations should be made before April 12 (LIB 8515).

EVANS AUDITORIUM

The first of a series of lectures by Dr. Albert B. Ferguson on "Roentgenology of the Bones and Joints" will be delivered at Evans Auditorium, 78 East Concord Street, Boston, on Monday, April 14, at 7:30 p.m.

The medical profession is invited.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital amphitheater on Tuesday, April 8, at 8:15 p.m.

PROGRAM

Presentation of cases.
Disabilities in Reading and Their Remedying. Professor Walter F. Dearborn, Harvard University.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 6

MONDAY, APRIL 7

12:15-1:15 p.m. Clinicopathological conference. Peter Bent Brigham Hospital amphitheater.

TUESDAY, APRIL 8

*9-10 a.m. Pancytopenia. Drs. William Dameshek and E. B. Miller. Joseph H. Pratt Diagnostic Hospital.

12:15-1:15 p.m. Clinicoroentgenologic conference. Peter Bent Brigham Hospital amphitheater.

8:15 p.m. Harvard Medical Society. Peter Bent Brigham Hospital amphitheater.

WEDNESDAY, APRIL 9

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*12 m. Clinicopathological conference. Children's Hospital.

4 p.m. Tufts Medical Alumni lecture. Dr. S. M. Jordan. Tufts College Medical School.

THURSDAY, APRIL 10

*8:30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital, at the Children's Hospital.

*9-10 a.m. The Problem of Vasomotor Rhinitis. Dr. L. R. Weinstein. Joseph H. Pratt Diagnostic Hospital.

*4:15 p.m. Public Health and National Defense. Dr. Harold D. Chope. Tufts Chapter of Alpha Omega Alpha. Tufts College Medical School, Room 5.

FRIDAY, APRIL 11

*9-10 a.m. Certain Aspects in the Diagnosis and Treatment of Contagious Diseases. Dr. E. H. Place. Joseph H. Pratt Diagnostic Hospital.

SATURDAY, APRIL 12

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*Open to the medical profession.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

- Williams Obstetrics* By Henricus J Stander, M.D., professor of obstetrics and gynecology, Cornell University Medical College, obstetrician and gynecologist in-chief, New York Hospital, and director of the Lying In Hospital, New York City Eighth edition 8°, cloth, 1401 pp., with 13 plates and 704 illustrations New York D Appleton Century Company, Incorporated, 1941 \$10.00
The Care of the Psychiatric Patient in General Hospitals By Franklin G Ebaugh, M.D., director, Colorado Psychopathic Hospital, professor of psychiatry, University of Colorado School of Medicine, and director, Division of Psychiatric Education, National Committee for Mental Hygiene, New York City 8°, cloth, 79 pp Chicago, Illinois American Hospital Association, 1940 \$1.00
Age Morphology of Primary Tubercles By Henry C Swensy, M.D. medical director of research, Municipal

Tuberculosis Sanitarium, Chicago, and research associate, Department of Physiology, University of Chicago 8°, cloth, 265 pp., with 73 illustrations Springfield, Illinois Charles C Thomas, 1941 \$5.00

Manual of Physical Diagnosis With special consideration of the heart and lungs By Maurice Lewison, M.D., professor of physical diagnosis, University of Illinois College of Medicine, consulting physician, Cook County Hospital and attending physician, Mount Sinai Hospital, Chicago, and Ellis B Freilich, M.D., associate professor of medicine, University of Illinois College of Medicine, professor of medicine, Cook County Graduate School of Medicine, attending physician and chief of Tuberculosis Staff, Cook County Hospital, consultant to the Chicago Municipal Tuberculosis Sanitarium, attending physician, University Hospital, and associate attending physician, Mount Sinai Hospital In collaboration with George C Coe, M.D., instructor of medicine, University of Illinois College of Medicine, associate physician, Cook County Hospital, and clinical assistant, Mount Sinai Hospital 8°, cloth, 317 pp., with 75 illustrations Chicago The Year Book Publishers, Incorporated, 1941 \$3.00

The Therapy of the Neuroses and Psychoses A socio-psychobiologic analysis and resynthesis By Samuel Henry Kraines, M.D., associate in psychiatry, University of Illinois, College of Medicine, and assistant state alienist, State of Illinois 8°, cloth, 512 pp Philadelphia Lea and Febiger, 1941 \$5.50

Anus—Rectum—Sigmoid Colon Diagnosis and treatment By Harry Ellicott Bacon, M.D., clinical professor of proctology, Temple University School of Medicine, associate professor of proctology, Graduate School of Medicine, University of Pennsylvania, visiting proctologist, St Luke's and Children's Hospital, proctologist, National Stomach Hospital, consultant proctologist, Mercy Hospital, and consultant proctologist, Paul Kimball Hospital, Lakewood, New Jersey Introduction by W Wayne Babcock, M.D., professor of surgery, Temple University School of Medicine Foreword by J P Lockhart Mummery, M.B., B.C. (Cantab.), F.R.C.S. (Eng.), emeritus surgeon, St Mark's Hospital, London, England Second edition 8°, cloth, 857 pp., with 507 illustrations Philadelphia J B Lippincott Company, 1941 \$8.50

Born that Way By Earl R Carlson, M.D. 12°, cloth, 174 pp New York The John Day Company, 1941 \$1.75

Electrocardiography in Practice By Ashton Graybiel, M.D., instructor in medicine, Courses for Graduates, Harvard Medical School, research associate, Fatigue Laboratory, Harvard University, and assistant in medicine, Massachusetts General Hospital, and Paul D White, M.D., lecturer in medicine, Harvard Medical School, and physician, Massachusetts General Hospital, in charge of the Cardiac Clinics and Laboratory 8°, cloth, 319 pp., with 272 illustrations Philadelphia and London W B Saunders Company, 1941 \$6.00

The American College of Physicians Its first quarter century By William Gerry Morgan, M.D., LL.D., Sc.D., professor of gastroenterology and emeritus dean, Georgetown University School of Medicine, Washington, D.C. 4°, cloth, 275 pp., with 36 illustrations Philadelphia American College of Physicians, 1940 \$2.00

Routine Practices Medical Service of the Peter Bent Brigham Hospital Compiled by the members of the Medical Service 8°, cloth, 145 pp Boston Peter Bent Brigham Hospital, 1940 \$1.00

The Medical Clinics of North America. Vol. 24, No. 6, November 1940: Philadelphia Number. With three-year cumulative index, Vol. 22, 23, and 24 (1938, 1939 and 1940). 8°, cloth, 325 pp., with 35 illustrations and 12 tables. Philadelphia and London: W. B. Saunders Company. \$2.67.

The Medical Clinics of North America. Vol. 25, No. 1, January, 1941: Chicago Number. 8°, cloth, 302 pp., with 35 illustrations and 11 tables. Philadelphia and London: W. B. Saunders Company, 1941. \$2.67.

Textbook for Male Practical Nurses. By Gayle Coltman, R.N. 12°, cloth, 215 pp., with 7 illustrations. New York: The Macmillan Company, 1941. \$2.00.

Hospital Formulary and Compendium of Useful Information. Compiled by the University of California. 16°, cloth, 270 pp. Berkeley and Los Angeles: University of California Press, 1941. \$2.00.

The Voice Governor: Give it a chance: Correct body mechanics does it. By Ralph M. Harper. 8°, cloth, 142 pp., with 40 illustrations. Boston: E. C. Schirmer Music Company, 1940. \$2.00.

BOOK REVIEWS

Surgery of the Hand. By R. M. Handfield-Jones, M.C. M.S., F.R.C.S. 8°, cloth, 140 pp., with 95 illustrations. Baltimore: Williams and Wilkins Company, 1940. \$4.50.

This book deals with surgical affections of the hand and discusses their diagnosis and treatment in detail. No new facts are presented, but the old ones are so important as to bear frequent repetition. The author has maintained throughout this work a healthy emphasis on early motion in infections of the hand. There is included a timely chapter on prevention of serious sepsis from minor injuries, and the use of the sulfonamide group is given an important place in the management of sepsis. It is interesting to note that the author recommends passive venous congestion in the treatment of acute lymphangitis—a measure that has been largely abandoned in this country.

This book will serve as a valuable reference for those who are learning about and those who are handling infections of the hand.

Arthritis and Allied Conditions. By Bernard I. Comroe, M.D. 8°, cloth, 752 pp., with 200 illustrations. Philadelphia: Lea and Febiger, 1940. \$8.50.

This meaty and profusely illustrated volume is probably the most comprehensive American survey thus far published in book form of the field of the rheumatic diseases. Over 2700 bibliographic references attest the wide scope of the author's review of the literature on these conditions. The illustrations are excellent, although largely chosen from other textbooks and monographs.

The forty-seven chapters not only deal with the pathology, etiology and general therapy of the different types of arthritis, but also describe in useful detail many of the special technics of administration, such as fever therapy, the use of gold salts, massage and exercises. Helpful warnings are given concerning the possible dangers to be escaped and the pitfalls to be avoided in therapy.

The reader is likely to wish at times that the author had been less dispassionate and had expressed in more definite phraseology his personal convictions and recounted his own experiences, as he has for example in his discussion of vaccine therapy. In reference to this much mooted question, the author believes from clinical evi-

dence that vaccine therapy is an "integral part" of the therapy of rheumatoid arthritis, but that an honest answer to the question, "How do vaccines work?" is, "No one knows."

The allied conditions cover a wide field, as the titles of certain chapters suggest, such as "Internal Derangement of Joints," "The Painful Shoulder" and "Painful Feet," as well as the subheadings, "Treatment of Sciatica," "Sprains," "Acute Bone Atrophy" and "Ganglion."

This book can be highly recommended as an excellent and up-to-date reference book that is worthy of the perusal of all internists and orthopedic surgeons dealing with these protean diseases, which are of supreme importance both medically and economically.

Pharmacology and Therapeutics. By Arthur R. Cushny, M.D., LL.D., F.R.S. Twelfth edition, thoroughly revised by C. W. Edmunds, M.D., and J. A. Gunn, M.D., D.Sc. F.R.C.P. 8°, cloth, 852 pp., with 66 illustrations. Philadelphia: Lea and Febiger, 1940. \$6.50.

Cushny's standard work on pharmacology and therapeutics has been thoroughly revised since the last edition four years ago. It is interesting to note that 1941 marks the forty-first year since this work first appeared. It has held its own for this long period, and is still a standard textbook. No greater tribute could come to any author than to have his book last through more than two generations of medical students and physicians. The student of today is thus reading the same book in his course of medical education that his father or those of that generation were brought up on.

Applied Pharmacology. By Hugh Alister McGuigan Ph.D., M.D. 8°, cloth, 914 pp., with 41 illustrations. St. Louis: C. V. Mosby Company, 1940. \$9.00.

Although the idea of this book is admirable, some of the execution is disappointing. It contains much useful information, but is not sufficiently complete, pharmacologically or clinically, to be as valuable as it might be. For example, the author fails to discuss the important differences in the disposal of various barbiturates in the body, and many inaccurate statements, such as that Luminal is used at bedtime in cases of epilepsy, are found. The idea and arrangement of the book are excellent. It is particularly valuable in giving the chemistry of some of the drugs.

Subsequent editions—with more careful editing—should make it a very valuable addition to any physician's library.

Principles of Surgical Care, Shock and Other Problems. By Alfred Blalock, M.D. 4°, cloth, 325 pp., with 13 illustrations. St. Louis: C. V. Mosby Company, 1940. \$4.50.

In this volume the author discusses the care of the surgical patient. He emphasizes the avoidance of complications but also includes their management when they arise.

The best part of the work is that devoted to shock or peripheral circulatory collapse. The author is an eminent authority in this field and has made many clinical and laboratory contributions. Although his main emphasis has been on the loss of fluid from the blood stream into the extracellular tissue spaces, his summary of the whole problem of shock is as clear and fair a statement as any that has recently appeared. The sections of the book on anesthesia and treatment may be found in any textbook of surgery, but seldom have been better documented.

The book will have an especial appeal to those who follow closely the trends in modern surgery.

THE CONVALESCENT CARE OF CHILDREN WITH HEART DISEASE DUE TO RHEUMATIC FEVER

A SURVEY OF THE PROBLEM OF THE CARE OF CHILDREN WITH RHEUMATIC HEART DISEASE*

PAUL D. WHITE, M.D.†

BOSTON

THE following three articles pertain to a joint five-year study of the problem of the care of children with rheumatic heart disease by the Children's Mission to Children, the Children's Cardiac Clinic at the Massachusetts General Hospital, and the Committee for the Home Care of Children with Heart Disease. This study began in 1934 and ended in 1939. The details of the survey are included in the papers, but a brief statement of the history of the interest of the three organizations in the child with rheumatic heart disease, and the general conclusions of the study are worthy of emphasis. The aim was twofold: to determine the value of the relatively intensive care of these children, and to ascertain the best way to utilize the resources available for such care.

The Children's Mission to Children, founded in 1849, has had an interesting and useful function, concentrating in the last forty years on the foster-home placement of children who could not remain with their own families. Since 1914, it has specialized in this vitally important work for children with medical problems, at the suggestion of Dr. Richard Cabot, who found that many children remaining for a long time in hospital wards became "institutionalized" and retarded in their physical and mental convalescence. Gradually the children with rheumatic fever and rheumatic heart disease made up an increasing proportion of the total, and bedcare began to be arranged. Five special nursing homes were developed, with medical supervision, nursing service, social case-work service, visiting teaching provided by the Boston School Department, occupational therapy, and last but not least, a truly homelike atmosphere.

With these resources and with a strong desire to contribute wisely, it was natural for the Children's Mission to join the other two groups in 1934 at the inauguration of the five-year study, which was undertaken to determine how best to care for the child with rheumatic heart disease.

The Children's Cardiac Clinic of the Massachusetts General Hospital was one of the pioneers in the country, starting out in 1912 under the guidance of Dr. Fritz B. Talbot, with the help of the Social Service Department of the Massachusetts General Hospital. Dr. Talbot's program included hospital care, supervision of bedcare at home, provision for amusement, convalescent homes, vocational guidance and prolonged supervision. The medical supervision of the clinic, begun by Dr. Richard S. Eustis and taken up later by the present writer, with the aid of Dr. Howard B. Sprague, Dr. Edward F. Bland, Dr. T. Duckett Jones and many others, has been continuously and intensively carried on with constant development and scientific contributions of value, and with very close affiliation with the House of the Good Samaritan. The most vital factor in the clinic's growth, however, has been the pioneer social-service work of Miss Edith M. Terry and her associates, Miss Katherine Breed and Miss Lorena M. Love, who have made world famous this aspect of the work of the Children's Cardiac Clinic. The question of the fundamental and ultimate value of all the time and money and effort expended in this work for children with rheumatic heart disease had often been raised in years past, and it was therefore natural for the clinic, with Dr. Bland's and Miss Terry's guidance, to join in the five-year study referred to above.

The Committee for the Home Care of Children with Heart Disease was organized under the

*This and the three following papers constitute a series from the Massachusetts General Hospital on behalf of the Children's Mission to Children and the Committee for the Home Care of Children with Heart Disease.

†Lecturer in medicine, Harvard Medical School, physician, Massachusetts General Hospital.

leadership of Mrs. Fritz B. Talbot to help fulfill the second and third steps in Dr. Talbot's program, which had been started by the Social Service Department in 1912. This committee took over the program in 1914 and has carried out its mission in the fullest degree, initiating and supporting the work of Miss Terry and her helpers for many years, and bringing to the homes and families of the children, as well as to the children themselves, help, cheer, instruction, material aid, and perhaps most important of all,—an innovation and yet a crying and obvious need,—expert medical attention. Thus it was natural for this committee to join the other two groups in the five-year survey.

The results of the study are of much interest, although hard and fast conclusions cannot be drawn, even from this intensive investigation, because of the short space of time and the small number of cases. A lifetime of observation, with thousands of children studied as carefully as these, would be required to permit dogmatic statements. It is also important to realize that only in the most recent generation has the extensive scope of the problem of the rheumatic heart been adequately appreciated. Due recognition must be given the following factors: the long course of active infection lasting for many months and frequently for years; the temporary heart-muscle involvement, with dilatation of the heart during the time of active infection; the good recovery that usually ensues despite chronic valvular deformity; and fresh recurrences of rheumatic fever, precipitated by many different episodes, most commonly by acute upper respiratory infections with the hemolytic streptococcus.

The chief lesson learned from this five-year study is that long and adequate bedcare for children with acute rheumatism or acute rheumatic heart disease is best carried out when the environment is most carefully arranged and homelike, with intelligent nursing, expert and readily available medical attention, food adequate in calories and vitamins, protection against colds, and effective measures in the form of recreational and occupational therapy to secure and to hold the co-operation of the children themselves. Treatment in the early days of the illness and when the disease is highly active may best be begun in the hospital, general or special (like the House of the Good Samaritan), with transfer after a few weeks, as circumstances allow, to the children's own homes if prepared and adequate, or to special foster homes such as those developed by the Children's Mission. The co-ordination of the large general hospitals, the House of the Good Samaritan, the Children's Mission, the Committee for the

Home Care of Children with Heart Disease and other resources in this service is one of the most important results of this five-year study. Equally significant is the vital contribution of bringing expert medical attention in addition to social service to the children's own homes and to the foster homes, a serious omission in days gone by. Another lack, which still exists, is that of adequate technical aid in the study of the blood of the children in foster homes and their own homes. In this disease all technical aid available is often needed in following the course of the infection. Leukocyte and erythrocyte counts, blood sedimentation rates and even electrocardiograms are helpful in doubtful cases and in decisions concerning the quiescence of active infection. Still another vital need and one of the most important problems of all, which has been as yet only partly solved, although its significance is fully recognized, is the protection of the child from colds, which are by far the commonest and most serious cause of exacerbations in subacute and quiescent cases of rheumatic fever. In institutions and in homes, such infections commonly involve many of the inmates, despite various precautions; experience to date has been that the best foster homes give the best protection. Finally, the morale and education of the children, very important factors in securing the co-operation of both children and parents in the treatment, have been maintained at a high level, with excellent results.

Is all this worth while? That important question, the first raised by all the groups at the beginning of the study, remains incompletely answered. Certainly from the standpoint of education of children and their families concerning this important disease, of enlisting their wholehearted co-operation, of making their lives happier and more useful, and of treating the disease more intelligently, great strides have been made. How many lives have been actually saved or how many hearts protected from greater damage one cannot say, since the data are as yet insufficient. Some children still die despite the most exquisite care of the sort outlined above, but as yet there has not been an adequate study of control cases, that is, cases which in the same environment and interval of time have been relatively neglected both medically and socially.* It is hoped and expected that our special care has reduced, at least somewhat, both mortality and morbidity in this group of children; even if it has not, the greater comfort and happiness that have resulted from this co-operative endeavor in themselves repay the cost and toil.

*An effort is being made to collect data from a control group for comparison with the findings in the group of children who have received intensive care.

RHEUMATIC FEVER IN CHILDHOOD*

With Especial Reference to a Five-Year Study of Home and Foster-Home Care

EDWARD F. BLAND, M.D.†

BOSTON

THE acute phase of rheumatic fever, when it occurs, usually subsides in a few weeks, but careful study has shown that signs of continued activity of the rheumatic process persist thereafter for months, and occasionally for years. Some of these signs are obscure and are evident only when diligently sought both by clinical observation and by laboratory tests. There is now general agreement that it is important to protect the heart by rest in bed, not only during the relatively short acute phase, but also throughout the illness until all evidence of rheumatic activity has subsided. It is also especially essential to protect the patient from respiratory infection during this unstable period, since recrudescences of rheumatic activity are usually precipitated by colds and sore throats. The acceptance of these two general principles in the management of patients with rheumatic fever has created new and formidable problems.

Facilities at home, or in hospitals when necessary, for treatment of the acute phase can usually be provided. The subsequent care for months in bed is necessarily more difficult to arrange. In many places this has become increasingly a community responsibility, since the disease prevails in families with low incomes whose homes are usually not suitable for prolonged bedcare. At present relatively few institutions are available for this special purpose; more are certainly needed. In the meantime, other necessarily less costly methods have been employed to provide this long rest in bed.

Because of this problem, a five-year program was undertaken in Boston in 1934 to study further the merits and limitations of convalescent care as provided at home and in foster homes under closer medical and social-service supervision than had hitherto been attempted. Under the guidance of a committee of which the late Dr. George H. Bigelow was the original chairman, certain foster homes of the Children's Mission were made available to the Cardiac Clinic of the Massachusetts General Hospital for a co-operative study of the problems involved. It was planned that when possible the patient's own home was to be

given first choice for convalescence. To this end, it was evident to those of us who had followed the course of clinic patients that in addition to medical supervision in the home a detailed study of individual and family needs in each case would be essential. Furthermore, past experience had emphasized the importance of happily occupying the minds of these youthful patients, for on this often depended the success or failure of otherwise well-planned therapy. Special attention directed to this phase of the program has yielded interesting methods, which are described in the papers by Miss Edith M. Terry and Mrs. Virginia B. Ebert.

The project as originally planned for five years has terminated, and although the joint program is continuing, it now seems appropriate to summarize the results to date with this specially studied group of patients.

TYPE OF CONVALESCENT CARE

During the five-year period from 1934 through 1939, children between five and fifteen years of age with rheumatic fever were accepted from the wards and clinics of the Massachusetts General Hospital for convalescent care. After social investigation of the home conditions and medical appraisal of the severity of the disease, a decision was made of the desirability of home or of foster-home care. Many factors, some only remotely related to the patient's illness, necessarily entered into this decision. The tendency throughout the study was to stress bedcare at home when it seemed at all feasible. Foster-home facilities were largely reserved for those children who required more expert supervision and nursing care than they could have received in their own homes. Medical-social workers have kept in touch with each patient at frequent intervals. All children have been visited by the physician in charge at monthly intervals, and oftener in special cases. The assistance of community-health nurses was invaluable in following the sicker group. Finally, it became evident soon after the project started that the intelligent management of these patients required ultimately the aid of certain minimal laboratory guides — the most helpful of which was the sedimentation rate of the red blood cells. The majority of these tests were made by a part-time technician

*From the Massachusetts General Hospital.

†Instructor in medicine, Harvard Medical School; assistant physician, Massachusetts General Hospital; visiting physician, House of the Good Samaritan.

who visited the homes, but some were carried out later at the hospital, when the patient's clinical improvement warranted a clinic visit.

After all evidence of infection had subsided, these patients were allowed out of bed, increasing the time an hour a week, and at the end of four or five weeks they returned to the outpatient clinic and from there their subsequent course was directed. The rheumatic process in this group was considered inactive when, in the absence of anti-rheumatic drugs, there were: freedom from rheumatic symptoms, such as arthritis, or arthralgia, abdominal and precordial pain, and nosebleeds; absence of signs such as pallor, nodules, chorea and erythema multiforme; a satisfactory general condition, which included a normal appetite and a progressive weight gain; a rectal temperature consistently under 100°F.; a normal sedimentation rate and white-cell count; and a normal auriculo-ventricular conduction time by electrocardiogram, corrected for the age of the patient.

Following this general plan 64 patients were studied. A certain number were accepted relatively early after the project started, because of previous rheumatic fever that, although inactive at the moment, was considered likely to cause trouble at a later date. Of this group there were 10 in whom the rheumatic process remained quiescent throughout the period of observation, and hence they may be dismissed without further comment. The remaining 54 patients required active treatment for rheumatic infection. In 38 cases the illness represented the initial attack, whereas the remaining 16 patients had had previous attacks of rheumatic fever.

A summary of the type of bedcare found necessary for this group may serve as a helpful index for those planning similar programs elsewhere. In 26 cases, or 48 per cent of the 54 active cases, ward care in the general hospital was necessary during the more acute stage of the disease. Two admissions were necessary for 6, and 1 patient was admitted three times. The average stay on the ward was four weeks. This represents a much shorter period of hospitalization than would have been necessary if the project had not been in operation. Foster homes were employed in 26 cases, but in only 10 for the entire duration of the convalescence; the remaining 16 patients were later supervised at home, after satisfactory adjustments had been made. In some cases a foster home was considered more desirable than the patient's own home for other than medical reasons—usually because of an unfavorable environment, somewhat less often because of a lack of understanding and co-operation on the part of parents, and occasion-

ally because of intercurrent illness in other members of the family.

In contrast to the children having foster-home care, there were 28 patients, 52 per cent of the active group, whose entire convalescence was supervised at home. For 14 of these, approximately four weeks of hospitalization were necessary at the onset prior to transfer home. Family physicians were available and participated in the management in 10 cases.

RESULTS

The duration of recognized rheumatic activity in this group of 54 children averaged eight months for each patient. In one case two and a half years elapsed before the infection was considered quiescent, and two other patients required a full two years of bedcare. It is of some interest to compare the duration of the disease in this group with the average period of hospitalization of a similar age group with the same disease at the House of the Good Samaritan in Boston.* At this institution the average stay for each patient during 1939 was six months. It must be remembered, however, that the latter group had received previous bedcare in general hospitals or elsewhere prior to admission to that institution, where the waiting list is often long and a considerable delay inevitable. It is a reasonable assumption that the actual duration of rheumatic activity in the two groups was not significantly different.

More important than the total duration of rheumatic activity is the relative severity of the patient's attack, since it is this feature of the disease that largely determines the mortality, as well as the degree of disability in those who survive. An arbitrary division of rheumatic activity into severe, moderate and mild has been helpful in studying the disease in other groups. By the same criteria, 17 (one third) of the 54 patients of the present group had severe rheumatic fever; in 26 (one half) the rheumatic fever was moderately severe; and in the remaining 11 (one fifth) it was mild. No case of pure chorea occurred in the study group. This distribution is a fair index of the relative severity of the disease in this section of the country.

In appraising further details of the clinical course of the group, it has again been helpful to have for comparison a considerably larger group at the House of the Good Samaritan during the same five-year period. A summary of the more important findings in these two groups is shown in Table 1. Certain striking differences in the outcome

Seventy-ninth Annual Report of the House of the Good Samaritan For the year ending December 31, 1939. 35 pp. Boston: House of the Good Samaritan, 1940.

as reflected in this table require special comment, since they are not, as at first glance one might suspect, due to the type of care provided, but rather to fundamental differences inherent in the two groups, evident perhaps only to those intimately familiar with both.

As indicated in Table 1, there were at the House of the Good Samaritan from 1934 through 1939 a total of 615 patients of essentially the same age as that of the patients in the five-year study, who also received protracted bedcare and even closer medical supervision. In the smaller group, 39 (72 per cent) developed rheumatic heart disease; the remaining 15 (28 per cent) showed no signs of car-

Good Samaritan	615	228 (37%)	387 (63%)	119 (30%)*

*Of those with rheumatic heart disease.

diac involvement. This compares with 387 (63 per cent) of the larger group who developed obvious rheumatic heart disease, and 228 (37 per cent) who remained in the potential rheumatic-heart-disease class. In interpreting the above comparison, it must be remembered that the latter figures are weighted in a favorable direction by a considerable number of patients with simple chorea, which is somewhat less likely to damage the heart than rheumatic fever.

A comparison of the mortality figures for the two groups reveals that in the smaller series 6 died as a result of congestive failure, all necessarily from the heart-disease group of 39, thus giving a mortality of 15 per cent. From the larger series of 387 with heart disease, 119 died, giving a mortality of 30 per cent, or twice as high as that in the smaller series. This striking difference in mortality appears significant, as, in fact, it is. The explanation, however, is obvious and is not related to differences in the type of care provided for the two groups. The series at the House of the Good Samaritan included a greater number of much sicker patients with a relatively poor prognosis, especially those with congestive heart failure, which were early recognized at the Massachusetts General Hospital as unsuited (except in special cases) for management either in their own homes or in foster homes. This very fact frequently accounted for their presence at the House of the Good Samaritan.

DISCUSSION

In view of the necessarily limited number of cases and certain evident differences peculiar to

the two groups, it is unlikely that a more detailed comparison would be significant. In fact, the results of such a detailed comparison, as already indicated, might be misleading. On the other hand, in attempting to evaluate this experience with the various types of care as provided in this community for children with rheumatic fever, the present method as it has developed over a period of years has proved adequate for the majority of cases. The results of this special study indicate that approximately 20 per cent, which includes the severe cases, ideally require institutional care for many months, both because of the more expert nursing care available and because of the necessary daily medical supervision. The presence of pericarditis, of pneumonitis or of congestive heart failure indicates in general a serious form of rheumatic fever in childhood, for which institutional management is indicated. For the remaining 80 per cent, foster-home care or supervised care in the patient's own home seems adequate. Either of the latter has, however, obvious disadvantages for careful clinical and laboratory study of the disease, but on the other hand, probably offers less exposure to respiratory infections, and hence fewer recrudescences of rheumatic activity, than care in a large institution. In many cases the small, well-run foster home is even better than the patient's own home. This is especially true if the units are very small and visitors infrequent.

When one attempts to appraise the relative cost of the different types of bedcare, certain obvious difficulties arise. The expense, in terms of patients a day, of maintaining a large general hospital, or even a smaller special institution, in contrast to a foster home, is necessarily high. In the present study and from data obtained from annual hospital reports, it appears that the daily cost of the three types of bedcare for a child with rheumatic fever in Boston is approximately as follows: Massachusetts General Hospital, \$7.50; House of the Good Samaritan, \$3.50; foster homes, \$1.90. The expense involved in the patient's own home is largely indeterminate and necessarily variable, but the economic advantage of the last is evident from the above figures.

In the present report and in the two that follow we have presented our experience to date with one method in the management of children with rheumatic fever. We believe that when both are available, a compromise between institutional care in some cases and foster-home or home care in others will prove in the end most effective, as well as economically sound. It is our belief that special institutions are needed in larger communities for the care of the sicker group and to serve as important centers for the study of the disease. At pres-

ent there is no convincing evidence that one type of management, in contrast to other methods, will influence differently the natural course of this disease, if certain minimal requirements are met. These requirements should include, in addition to adequate bedcare, a studied approach to each patient and his family, supervised recreation and education during convalescence, all possible protection from respiratory infection during this period and, finally, medical supervision by physicians well acquainted with the persistent nature and recurrent proclivity of this chronic disease inaptly called "acute rheumatic fever."

SUMMARY

Special study during five years of home and foster-home care for children with rheumatic fever indicates that, when well organized, it is adequate for the majority. The sicker patients need prolonged institutional care.

There appears to be no significant difference in the duration and course of the disease in this home and foster-home group and in the group who received similar care in an institution.

The economic and social advantages of home and foster-home care are evident.

A MEDICAL-SOCIAL PROGRAM FOR THE CHILD WITH RHEUMATIC FEVER*

EDITH M. TERRY†

BOSTON

THE special program for cardiac children at the Massachusetts General Hospital was developed, in conjunction with the already established Social Service Department, soon after the Pediatric Service was initiated in 1911 with Dr. Fritz B. Talbot as chief. At that time Dr. Talbot‡ outlined the following as essential for the adequate care of the cardiac child: hospital care for the acutely ill child; supervision of subsequent bed-care at home; provision for amusement; convalescent homes; vocational guidance; and prolonged medical and social-service supervision.

Although the growth of the clinic during the last thirty years has necessitated changes and promoted new activities, the main features of Dr. Talbot's original recommendations have also served as the basis of these newer developments. The general problem presented by the clinic child with rheumatic fever and heart disease is, broadly speaking, threefold: these are medical and social care, adequate education and suitable recreation.

The following is an outline of the methods employed and the resources available to us in Boston:

MEDICAL AND SOCIAL ASPECTS

Hospitalization has been provided, when it seemed desirable, at the Massachusetts General Hospital, or at the House of the Good Samaritan, for patients during acute episodes of rheumatic fever.

Placement in medical foster homes has been arranged

*From the Cardiac Clinic, Massachusetts General Hospital.

†Medical-social worker, Cardiac Clinic, Massachusetts General Hospital.

‡Talbot, F. B. *A Consideration of the Social Service Work of the Department of Diseases of Children in the Massachusetts General Hospital*. 2 pp. Privately printed, 1912.

by the Children's Mission to Children when the home situation has been found, after investigation by physician and social worker, to be detrimental to the patient's recovery.

Medical-social home care, a term that means joint supervision by physician and medical-social worker, is a service given at home to patients in bed who are unable to afford a private physician. Home visits, arranged by the social worker and made on a monthly or bimonthly basis, not only secure for the patient consistent medical care similar to that given by a family physician, but promote a better understanding on the part of the physician of the social implications involved in treatment, and make possible frequent conferences with the social worker.

Nursing care at home has been provided by visiting nurses, supported by the community. In addition to instructing the mother in bedside care, these nurses have supervised the making of temperature and pulse charts and the following of the diet recommended by the physician. They have also kept the physician and social worker in touch with new developments as well as the general progress of the patient.

Medical-social case work has been considered the fundamental function of the social worker since the establishment of the clinic, and has included a study of each new patient and the use of available resources for each. Such studies are reviewed from time to time to keep in the foreground the individual approach.

Consistent follow-up of the whole group has been carried on by the clinic social worker. In addition to routine postcards, letters and home visits on patients who have failed to report when requested to do so, this service has included arrangements for clinic appointments, and laboratory service as needed. One hundred per cent follow-up is the aim of this service, and during 1939, on a group of 263 patients who had been at the House of the Good Samaritan, we were able to report on all but 1. At each clinic visit a brief interim history of medical and social

conditions has been taken by the social worker in accordance with clinic procedure.

EDUCATIONAL AIDS

Co-operation of home teachers has been secured through the public school system. By means of a home teaching service, when the acute phase of rheumatic fever is over children in this group have been able, in the majority of cases, to make their grades and on their return to school go on with their classmates. Failure to go on with one's classmates presents one of the greatest problems the cardiac child has to face, and one that the adolescent child is often unable to accept.

Tutoring by college students Repeated respiratory infections, with consequent days in bed, often interrupt the school program. Frequently children find that they are facing failure in one or more subjects because of such interruption. To prevent such disaster, we have been able with the approval of the schools, to provide for some of the children in this group tutors from nearby colleges who, by individual instruction, have made it possible for the child to surmount such difficulties.

Cardiac Summer School For the last few years, in co-operation with the Radcliffe College Appointment Bureau we have held during six weeks of the summer a school for cardiac children that has supplemented the work of the home teachers and the tutors. This school, held on the college grounds six hours a day and four days a week and carried along on progressive lines, has not only helped children educationally, but has provided suitable recreation for a group who are not at the time physically equipped to fit into ordinary camp life.

The school is carried on under the direction of a teacher in the public school system, the cardiac occupational therapist and tutors provided by the college. In addition to the usual grade subjects, opportunity for individual expression is given through various group activities. The summer school program also includes a hot lunch at noon planned by the hospital dietitian, and an hour's rest period out of doors.

School nurses Problems of patients returning to public school have been met through the close co-operation of the school nurses, who have made adjustments regarding elimination of stair climbing, restriction regarding school activities such as gymnasium and sports, noon rest periods, lunches and dental care.

The *Mothers' Club*, group activity for the enlightenment and education of mothers undergoing the anxiety of caring for children who are ill or otherwise handicapped, has an important place in cardiac rehabilitation. The club meets monthly. In addition to a brief talk on problems relative to the care of the cardiac child, opportunity is given during the tea hour for members to discuss among themselves their individual problems. The mother whose child is in bed goes back with new courage after hearing from others about their children back at school.

RECREATIONAL FACILITIES

The *In Bed Club*, with its membership of children facing like restrictions, its badge, its magazine to which the children contribute, and frequent contacts by mail and home visits, has tended to lessen the sense of isolation, especially for those in bed at home, so common to all children removed from an active group. In addition, it has been an aid in medical treatment by keeping the patients happy and contented during their convalescence. The *In Bed Club* has spread to include chapters in this country and abroad.

Occupational therapy has also played an important part in treatment, not alone for the patient, but indirectly for the family as well. Gay colors, interesting crafts, the ability to give as well as to receive, and best of all, occupation for otherwise dreary hours, not only help to keep up both the patient's and the family's morale, but have therapeutic value. This therapy has also helped to guide patients along lines of possible later vocational adjustment through study and development of their interests and abilities.

This program had been operating at the Massachusetts General Hospital for a period of years before the joint study with the Children's Mission began. Although it was considered reasonably successful, it was recognized that there was a need for greater unity and continuity of the various services, of more careful work with a smaller selected group of patients, and of evaluation of needs and services from the point of view of both the individual cardiac child and the total community program. To carry out these purposes, the hospital and child placing agency evolved a joint project that would make use of all existing resources of the previous program but would enlarge the opportunities for service.

As a means toward this end a working team was appointed and acting under the direction of a steering committee representing the co-operating organizations, was empowered to carry on the demonstration for a period of five years. This group consisted of a physician in charge of the medical aspects, a medical social worker from the clinic, a social worker,* who was added to the staff of the child placing agency, and an occupational therapist.

For this five year study 64 children under eighteen years of age were selected from the Children's Cardiac Service. Their residences were as follows: 31 from Boston, 12 from the metropolitan area outside Boston; and 21 beyond this area. There were 33 boys and 31 girls. The nationalities represented are indicated by the parentage: Italian 25, American 21, Irish 6; Russian (Jewish) 5; Canadian 5; Portuguese 1; and Greek 1. The religious affiliations were: Roman Catholic 48, Protestant 10, Hebrew 5, and Greek Orthodox 1.

Unusually consistent medical care and periodic evaluation have been possible for this group through the services of the physician in charge, who has known all the patients individually and who, by frequent conferences with the social workers, has kept in touch with the social as well as the medical aspects of each patient's situation.

The two social workers agreed on certain functions that each was to perform in the project. The

*During the earlier part of the project it was a children's worker in the latter a worker trained in medical social work.

medical-social worker in the clinic assisted the physician in the selection of children suitable for this project out of the total group of ward and clinic patients. Selection was largely limited to those whose prognosis, both medical and social, was sufficiently favorable to justify the expenditure of the time and money.

A further role of the clinic worker was to act as liaison between physician, child-placing agency and hospital. Her third responsibility was to follow those patients when they no longer required service from the child-placing agency, either because they had made a satisfactory recovery, from both the medical and social standpoints, or because they were not responsive to social treatment.

The special worker assigned from the child-placing agency conducted a careful study of all cases accepted. She also made a special effort to understand the emotional reactions of these patients and their parents to the disease. Through frequent interpretation and a close and continuous relation, she alleviated anxiety and helped them toward an acceptance of chronic illness without

undue emotional tension. She also aided with other personal adjustments that customarily come within the social worker's field.

From the social worker's point of view concerning this joint study, in which the medical and social analysis and treatment of the child have been carefully and thoughtfully correlated, lessons have been learned and valuable material gathered concerning the social, economic and educational aspects of the problem of cardiac children. One phase of the service, which has previously been given less attention than seems to us necessary, is the meaning of heart disease to the child himself—this will be considered in the following paper.

SUMMARY

The manifold experience of the Children's Cardiac Clinic of the Massachusetts General Hospital in meeting the social, educational and recreational problems of patients with rheumatic fever and rheumatic heart disease has been presented in summary form.

SOCIAL SERVICES TO CHILDREN WITH RHEUMATIC FEVER*

VIRGINIA B. EBERT†

BOSTON

THE two major interests of this co-operative five-year study have been to ascertain a rounded picture of the varied needs of the rheumatic-fever patient, and to investigate how these needs may best be met through community services. Special attention has been paid to the individual difficulties due to illness and common to this group of patients.

Care in the hospital for the acute episode had been the experience of most of our patients, the average stay being approximately four weeks. Social study begun in the hospital was completed by the children's agency worker, and the final plan for care was decided on jointly. The doctor described in the referral the type of care needed for the individual patient, and the medical-social worker attached to the children's agency investigated available possibilities to help in the decision of where that care might best be provided. Thus choice of aftercare depended on the individual situation, as well as on the physical need. Factors influencing the direction of care were often complex, and the original study of the situation was helpful in avoiding later pitfalls.

Aftercare was provided either in the patient's own home with close guidance of the children's agency worker to ensure careful following of the doctor's recommendations, or in medical foster homes, which will be described and discussed later. A well-integrated medical service was available for the patient by the same supervising physician of the hospital staff, whether the child was in his own home or in the medical foster home. The co-operation between the physician, the hospital social worker and the children's agency worker represented a closely knit, continuous service to the patient throughout the illness. During quiescence of the infection, consistent periodic follow-up in the clinic served to keep the patient co-operative and aware of his part in preventing recurrence. The continuity of medical supervision ensured a high quality of care, and resulted in the greater satisfaction and confidence of the patient. The personnel aiding the physician and the numerous and invaluable contributions by various community services have been described in the preceding paper.

CARE IN THE CHILD'S OWN HOME

The aim with the study group of children was to keep them in their own homes, since it was thought

*From the Children's Mission to Children.

†Medical-social worker, Children's Mission to Children.

that care for an extended illness in the child's own home, when feasible, has many advantages. Thirty-eight of the 54 cases continuing in our care were followed at home.

In general, the child is most content in his natural, family surroundings. Anyone who has watched closely the reaction of children removed from their own homes knows the psychic trauma such an experience often entails. Parental love and family surroundings offer to the child the only security in a world as yet untried. It is sometimes a big request to ask him to be content with care by strangers. Some children, after placement has been explained and described to them and after they have been given a chance to participate in the planning, will bravely and calmly try this new experience—many of them, of course, finding compensatory pleasures and interests in the new home. Other children, for reasons of their own,—and they are usually good ones,—cannot calmly accept this separation, as shown in the following case:

Billy chose an unfortunate time to be born. His father had lost his job for the first time one month previously. His 10-year-old sister was at the time critically ill with rheumatic fever. The family had recently moved to a house in a far-outlying district. Electricity and convenient transportation, to which the family had been accustomed, had not yet penetrated the new section. There were many hardships in rebuilding and making a home. Billy's birth was difficult, and the mother's memories of the event so painful that she planned that he would be the last. Through various interacting causes, Billy assumed the position of the most troublesome of the four children until, when he fell ill with rheumatic fever and chorea at 8 years of age, his mother was only too glad to urge placement for him. Although he objected, he was placed because of the inaccessibility of the rural home to services for the ill child. As he began to get better, his energy went into an increasing vent of behavior problems, and on discharge he worked out a surprising amount of aggression against his family. He taunted his mother with the accusation that she did not want him at home anyway, and asked why she had brought him back. Placement was certainly not responsible for the sudden development of a highly aggressive personality, but one needed to understand a little more of this child's status in the family—a youngest, most insecure child—to prevent placement from augmenting already existing problems. His feeling of not being wanted was accentuated by placement.

Another gain of home management is that, under the friendly interest and guidance of the doctor and social worker, the family and the patient learn to care for all stages of the illness, and to plan a good health program to prevent recurrences. Thus an obvious advantage is that the family and the patient learn together how best to care for chronic disease. There is an opportunity, then, for the family to develop a feeling of adequacy in handling its own situation, rather than acquiring a feel-

ing of frustration, which may result from relieving the family of desired responsibilities, or the equally harmful overdependence of the family on outside persons to take over the care of the sick member.

A further advantage in keeping the child at home during prolonged bedrest is that he does not suffer a loss of place in the family group. Some children return after extended medical placements virtual strangers to baby brothers or sisters who have grown and have actually forgotten the patient. Older brothers and sisters are shy and reserved with the newly returned child. It is not that irreparable damage has been done,—children soon find their old footing in common interests,—but the patient's sense of isolation and difference from the group of normal companions is called to conscious recognition by these painful experiences. This is illustrated by the following case:

A 15-year-old Italian girl refused placement from the hospital in a nursing home for the third time. Unalterable overcrowded conditions existed in her own home, because of the multitudinous and merry family group of nine living on a marginal income. Since she had missed the birth of the last baby, she wanted to be on hand for the next one. She remarked woefully to the worker: "People are always planning visits to meet me at home, and by the time they get there I'm either in the hospital or the foster home. They know me by description, I'm the sick one. But they never see me. I'm just a make-believe Stella." She was followed medically at home. Her physical condition to date (now two years later) has been unusually good, despite the crowded home conditions.

The social worker's most active period of service to the family during the patient's home care is in the early stages of the illness, when parents are eager to learn what constitutes good care, and when a schedule conducive to recovery can be worked out with them. Questions are many, since misunderstandings, doubts and fears of both the patient and the family give way in many cases under simple, truthful interpretations of the disease to understanding and a calmer, rational acceptance of the illness as inconveniencing and difficult in some ways, but within the range of comfortable adjustment.

Help in planning for the patient's care at home includes introducing the services of the visiting nurse, the results of whose consistent watchfulness of physical findings are recorded for the physician. Accessory services of the nurse include suggestions regarding the patient's diet and practical ways of making the patient more comfortable. These, in addition to her professional skill and friendly interest, are valuable aids to the family. The visiting teacher brings the needed antidote for frequent worries over school retardation. Worries that are not founded on previously existing school difficulties vanish with progress in lessons. All but 2 of the

54 children had home teachers provided through the public-school system. Six had the additional help of volunteer tutors, and 17 attended the summer school organized by the Cardiac Clinic. The occupational therapist on the staff of the Children's Mission brings the patient vital and interesting substitute activities to offset the sense of isolation and restriction. The studious or creative patient can be encouraged to make the most of this enforced period of leisure in learning new skills, such as modeling, weaving or wood carving. Vocational interests in some cases are found, or suggestions of a change of interest more in keeping with the patient's handicap subtly encouraged. The occupational therapist often finds her program demanded by healthy members of the family, who feel left out of fascinating and worthwhile handicrafts. The patient, instead of losing his particular place in the sun, has gained a new prestige. The occupational-therapy program, by creating a happy atmosphere of activity, geared to the child's physical capacity, helps to prevent excessive self-interest.

Plans for the patient's care at home may include material aid for the added stresses of illness among families of marginal income. Twenty-two families in the study had adequate incomes and physical resources for care. Thirty-two families had borderline or inadequate incomes. For the latter, if they desired the service, budgets were worked out on the basis of Community Health Association estimates of the total needs of a family according to size. Financial aid was frequently secured from the proper agency to ensure adequate food and living quarters.

While these long-time adjustments are being arranged, the extra expenses of illness, which a family is unable to meet, are provided by the children's agency. Much unhappiness and sense of failure, which can be oppressively acute, is avoided for those parents whose intelligence and capable management make them adequate to meet the demands of the illness, but whose pay check for one complicating reason or another fails to cover the requirements of their families. Expressions of gratitude from parents who were helped to provide adequate care at home, have made clear the earlier feelings of many — the unhappy resignation of being unable to provide essentials for a child, particularly a sick child, and a feeling that once more inadequate resources would force them to fail as parents. These general case-work services can help with environmental changes, thus easing necessary long-time bedcare, such as a move permitting more convenient accommodations for the patient's care. Many and varied are the needs during illness in the lower-income groups.

The types of families that can be depended on to provide proper care for the patient are for the most part easily distinguished in those first weeks of frequent visiting. One group of parents is represented by those whose questions and problems are natural in the face of meeting a new situation, and are alleviated through developing capacity to carry out medical recommendations. With the initial discouragement at prolonged illness somewhat abated, many mothers show creative imagination in handling the more complex and newly developed behavior often associated with illness, becoming interested in discussions with the social worker, and consciously offsetting undesirable family attitudes or actions.

There are two groups of parents whose cooperation is not so dependable. One is the group in which marked emotional instability exists. By marked instability I mean those homes where interest in the patient and in the good of the family as a whole does not come before a parent's preoccupation with personal dissatisfactions. Within a short time it is possible to evaluate the parent whose efficiency is impaired and who will hamper the patient's progress by neurotic attitudes. Patients from these families are best placed in foster homes, where a strong sense of responsibility for their own health care may be developed, since it is likely that parents disturbed by personal difficulties cannot offer sane guidance through ensuing years. Another group of children who seem to fare better for a period of recovery in the foster homes are those from homes where parents are simple and childlike, because of limited experience and background resulting in an inability to recognize or to handle the usual parental responsibilities.

The complicating problems of some parents may be open to a degree of change or relief through services offered by the medical-social worker. Psychiatric services can be used for others. To minimize as much as possible the effect on the patient, one may have to continue with those parents whose problems affecting the patient's adjustment and care are not open to relief through either of these channels.

During illness, the greatest development of the family's potential strength comes through the vital interest of the worker in the patient, and in the family's progress toward confidence and competence in handling the situation itself. This source of strength to the family is second only to faith in the physician and the security of adequate medical care.

CARE IN MEDICAL FOSTER HOMES

Medical foster homes have been used when uncontrollable situations existed in the patient's own

home, or consciously as an aid in educating the patient and the family in the recommended long-time care for this chronic illness. Twenty-six children were placed in foster homes once during the five years; 13, twice; and 1, thrice. The length of time spent in the foster home ranged from one to sixteen months.

The foster homes used are private homes in residential districts. They accommodate from 4 to 15 children in each, and are run by trained nurses under medical supervision. Initial investigation of the prospective home is made by the home finder of the Children's Mission, and periodic evaluation of the home is made on the basis of experience in working with the foster mother, so that a high standard is maintained. The foster mothers and their assistants are usually motherly persons, who prefer to maintain a comfortable and attractive nursing home to doing private or institutional duty. Needless to say, they like children and have some insight into the sick child's problems, as well as an ability to learn daily how best to handle the behavior components of illness, induced by resentment, discouragement, fear and other emotional attitudes. The social worker's job here is to further the foster mother's understanding of the child, and to help the patient with his difficulties. The foster homes are under the administration of the children's agency, which has the responsibility of approving and supervising them as well as paying for the service of the foster mother.

Proper health routine within the medical homes is well established, and becomes a habit with the children. There are usually three to four children in a room, depending on its size. Adequate air, light and space between the patients' beds are provided. The rooms are gay, colorful and comfortable. Space for the immediate isolation of respiratory infections is reserved in each home. Foster-home care for ill children has been a natural development to meet the recognized need for congenial, homelike surroundings for their best growth, physically, emotionally and intellectually.¹

A contribution of the foster home to the child's physical comfort and progress is the purposeful, gradual education of the patient to assume responsibility for the proper health care within his own home. If the child is a responsible and praiseworthy partner in his own health program, the resentment and consequent rebellion, which so often impede physical progress, are offset.

DISCUSSION

Whether in his own home, or the foster home, helping the child to establish a program correlated with the long-time needs created by chronic illness, continues to be the social worker's respon-

sibility after recovery from active infection. The worker attempts to establish on her own work sheet, as it were, a clear idea of environmental influences on the patient's illness, based on factual material, observed actions and expressed attitudes, so that she may offer constructive guidance toward adjustment to the disease. Medical-social workers are agreed that their most important activity, because it is the fundamental understanding on which the specific services can be geared to meet the child's need, is the long intricate process of knowing well the patient himself in relation to his family and associates. Individualization, or an attempted understanding of what kind of person one is serving, is a basic social-work concept.²

One must daily face the practical necessity of knowing family attitudes and relations for a correct evaluation of the patient's attitude toward the illness. The child's reaction to disease is frequently a reflection of emotional attitudes for which the groundwork is already laid. It is important that these attitudes should not be more crippling than the degree of heart disease suffered. Any chronic illness frequently constitutes a focus of attention and can result in an accentuation or progressive development of a number of character traits, including dependence on others or an incapacitating fear of illness. One must understand how and why the patient is responding to disease, if one hopes to prevent or to lessen varying degrees of maladjustment in those children whose life experience tends to set the stage for unwholesome or exaggerated attitudes toward illness. If one is able to make the most of this opportunity, an early diagnosis of the social component of illness will result in a plan of treatment that is a vital, growing process.

An example of a social diagnostic statement made three weeks after a case had been accepted shows how the interrelated factual material—growing clearer, as time goes on—sets the trend of treatment from the earliest planning for the patient. It is recognized that human material of this sort is not subject to criteria of absolute definiteness as certain types of medical diagnoses are, but rather that one is dealing with feelings, attitudes, actions and influences subject to constant flux and change. The social diagnostic statement is a useful, flexible and, in large part, valid guiding post for action by the social worker in helping the patient to make his best adjustment to chronic illness. This early social diagnostic statement, although still lacking essential knowledge of the patient, is a beginning and permits constructive handling of individual reactions to rheumatic fever, as shown by the following case:

A 14-year-old, Roman Catholic boy of Irish parentage, in his first year in high school, was the oldest of three children. Finances were adequate, covering the essential needs for the family. The father had lost his status in the white-collar merchant class because of the depression, but had held a responsible laboring job consistently since that time. The family lived in its own house, maintaining excellent standards of care and household routine.

The patient had a severe attack of rheumatic fever, and was uncertain and confused about his illness. Placement was asked by the mother, because the boy refused to recognize the need of medical restrictions and the mother feared that she could not control him at home. His greatest interest was in sports, in which he had taken an active part, and in which he had entertained the idea of a life career. The patient showed anxiety and great interest in what rheumatic fever would mean to his future program. He had bet contemporaries on the ward a dime that, contrary to their explanations, rheumatic fever had no possible connection with heart trouble.

Coupled with the patient's refusal to accept illness was disappointment over possible school failure because of absence. This feeling was accentuated by the family's tendency to stress schoolwork with the patient more than with the other children, because he was a borderline student. There was indication in the school record that his capacity was average, or above.

Another social component of the patient's illness was worry over the results of his sickness on the family's economic security. There was evidence of further disturbance on the patient's part, because of conflict with his mother. Her "old-fashioned" standards and management were opposed to the patient's ideas, which were based on practices of his schoolmates. Evidence of the patient's complaints was found in the mother's oversolicitous supervision of the boy's hospital experience, as well as the fact that the only point of dissension between the patient's parents was the mother's discipline of him. It seemed that the patient's dissatisfactions with his mother's discipline had a legitimate basis.

Treatment plans for this patient included efforts to modify these factors, as well as to provide for immediate practical needs.

Our aim,³ then, is to promote the patient's adherence to the medical program by helping him

to understand and to work through his own specific problems in relation to illness and to facilitate a realistic acceptance of heart disease and possible chronic illness, so that he may pursue, to a reasonable degree, vocational interests and social satisfactions in spite of a limitation of activity.

SUMMARY AND CONCLUSIONS

The social service offered within the patient's own home, permitting the recovery program for rheumatic fever to be carried on there, is described. The major advantages of care in the child's own home are considered to be the patient's greater contentment, in most cases, and the development, through education and encouragement, of the family's and the patient's confidence and competence in handling the problems of chronic illness. Home care is considered unsuitable mainly when parents are markedly neurotic, or childlike and undisciplined.

Medical foster homes have been developed to offer homelike and wholesome surroundings for the ill child. They are used especially for the definite educational purpose of training the child to assume responsibility for his own health care, thus tending to prevent recurrence of active rheumatic fever. Foster-home placement is indicated not only for training the patient in a health program but also when unalterable conditions not conducive to recovery exist in the child's own home.

PSEUDOCYESIS*

ROBERT N. RUTHERFORD, M.D.†

BOSTON

PSEUDOCYESIS, or spurious pregnancy, has been an affliction of queen and commoner with reverberations in many fields from domestic to theological.

Good, in his *System of Nosology* (1823), first coined the term from *pseudes*, false, and *kyesis*, pregnancy. Writers from Hippocrates to the contemporaries have lavished on the syndrome descriptive adjectives that vary from "brain pregnancy" to "wind in the bowels." Today it is defined as a condition in which the signs and symptoms of pregnancy appear or are simulated in whole or in part. The clinical picture may be so exact as to deceive both patient and physician. One may add that this affliction is usually regarded as purposive on the part of the patient.

HISTORICAL ASPECTS

Bivin and Klinger¹ in their classic monograph on the subject have provided an excellent historical background. Hippocrates² encountered twelve such patients in his practice in 300 B.C. As interest continued, there was considerable speculation as to the etiology. Each man proposed his views according to the medical knowledge of his day, although many writers were not concerned with its cause. Hippocrates² wrote:

When the matrices taking in the air coming from the stomach which supplies it, swell, and the women believe themselves pregnant, or else, if the menses not flowing, accumulate in the matrices and stay suppressed for some time, there is continual flux in the matrices, sometimes with air coming from the stomach, some times from the effect of heat, and then again women imagine they are pregnant, seeing that the menses are suppressed and the matrices swollen.

William Harvey³ suggested that both the brain and the uterus were filled with an "imagination (phantasma)" brought about by coitus or a conception without result.

Mauriceau⁴ (1721) speaks of a "false great belly" engendered by nothing but wind mixed with waters. "This false great belly . . . is often caused by wind which blows up and distends the womb and which women often times discharge with as much noise as if it came from the fundament. Sometimes it is nothing but water gathered there in such abundance, as some have been seen to void a pail-

full without any child, though they verily believed they were with child." Girard⁵ (1801), of Lyon, thought "the impulse given to the uterus by coitus sufficed to give birth to signs of false pregnancy, although the sperm had not been absorbed by this organ. The seminal fluid gives life particularly to the uterus which reacts on all the system as if she had something in this cavity."

Schmitt⁶ (1857) was the first to consider the subject on a hysterical basis, as being due to the effect of an excited imagination.

It is as if impregnation proceeded from the brain, a matter which can only be comprehended, and that obscurely, from the intimate polar conception (sympathy) known to exist between the cerebral and sexual systems, together with a degradation (depression) of the cerebral into the depths of the ganglionic system, together with a magnetic effort on the part of the latter to break through the limits of individuality (or those allotted to it).

The majority of writers believed that this was not self-deception, and not entirely a product of the imagination, for it is a phenomenon repeatedly observed in animals—creatures reputedly without imagination.

Underhill⁷ (1877) looked on pseudocyesis as a mental aberration and but one of a number of symptoms of such imbalance:

The delusion in all these cases is a false interpretation of bodily sensations occurring for the most part in the abdominal viscera. Air moving about in the bowels, whether giving rise to tympanitis or not, is the most frequent source of sensation which the disordered brain falsely recognizes as movements of the child. Or . . . simply the twitchings of the abdominal muscles may be mistaken for the sensation of quickening, the disordered mental faculties being unable to appreciate the difference. . . . Simple distention of the abdomen, whether from intestinal gases or graver causes, may also give rise to a false belief in the existence of utero-gestation.

Meigs in his *Diseases of Women* (1879) easily disposes of one school of physiologic thought: "It is against physiology, against pathology, and it flies in the face of common sense, to talk of a collection of wind distending a material like the womb. Air is too subtle to remain quietly locked in a bottle that has no cork in it."

Gradually the pendulum overbalanced to the "mechanism of neurosis" wherein guilty serving girls and guilty wives built up case after case

*From the Boston Lying in Hospital.

†An assistant resident, Boston Lying in Hospital.

This passed the extreme phase soon, however, and Charcot (Bouchacourt,⁸ 1892) said, "Hysterical, no; mental, yes." Maryanchik⁹ (1894) indicted the obesity of the rich as well as the flatulence of the poor. Mitchell¹⁰ (1895) wrote, "Women suffering from pseudocyesis are in no sense of unsound mind, nor is their illusion to be classified with the delusory and obstinate belief as to their pregnancy held by some of the insane." Of the childless woman at the climacteric, he wrote, "The illusion of pregnancy in such females is a flattering one."

Donald¹¹ (1897), of London, divided phantom tumors into five classifications: those associated with pelvic peritonitis, the normal climacteric period, a pathologic menopause, amenorrhea and a rapid development of fat in young women as a symptom of pure hysteria. Janet,¹² Lemesle¹³ and Le Menant¹⁴ all emphasized the correlation with hysteria and neuroses. Pohl¹⁵ (1901) believed that knowledge of the symptoms of pregnancy was essential in the development of the entity. Berkeley¹⁶ (1922) explained the mechanics of the abdominal distention thus:

Diaphragmatic contraction, pressing down upon the abdominal contents and making them bulge. . . . It might be supposed that this diaphragmatic spasm is really voluntary, but there is no doubt it is not entirely so. No person could voluntarily keep up such a muscular effort as is required to produce the enormous swelling seen. It is strictly a condition in the same category as hysterical fixation of a joint.

Haultain¹⁷ (1926) gives the cause as "reflex nervous" from mental perversions met with in sterile women at menopause, in women newly married who are desirous of offspring, and in the unmarried women who have had illicit intercourse; other "reflex nervous" causes are from diseases of the generative organs, such as fibroids, ovarian cysts and ascites. Williams¹⁸ (1924) wrote: "Occasionally women, usually at about the time of menopause, develop abdominal enlargement and, wishing for pregnancy, get a firm idea that this has occurred. The symptom complex of amenorrhea (due to menopause), enlarged abdomen (due to deposition of fat plus hysterical depression of the diaphragm), sensation of fetal movements (consciousness of intestinal movements), and so forth, can easily delude a woman."

In 1814 Joanna Southcott, a sixty-four-year-old virgin prophetess, announced herself with child by the Holy Spirit. Gooch¹⁹ (1859) quotes her physician, Dr. Reece, as writing, "When these symptoms [enlargement of the breasts and abdomen] were accompanied by a sensible motion of the womb, I could never hesitate in pronouncing it a case of pregnancy, and this was actually my opinion of her situation." Eminent opinion was di-

vided. Her followers, some hundred thousand, awaited their new Messiah joyously. Two months after the date set for her confinement, Joanna died. An autopsy was performed in the presence of fifteen physicians, and there was no trace of the tumor that Joanna had felt during her life.

A number of interesting stories are told—one of a young man who was forcibly married by his bride's brothers. The young man's rage was reported as "boundless" at discovering that he had been compelled to marry her on a false supposition. Poetic justice was dealt a number of "seducers" in the past according to tellers of the obviously enjoyed cases.

Many writers suggest that the final factor of the symptom-complex is a physician who mistakenly confirms the patient's hopes, fears, or suspicions!

ETIOLOGY

Each writer on the subject has contributed a somewhat different explanation. The older writers lean toward physiologic explanations, whereas the more recent point out the possible psychogenic basis.

Bivin and Klinger¹ (1937) have collected all the 425 cases appearing in the literature,—excluding mental and physical disease,—and have added 19 cases. Their study is complete, and their figures on these 444 cases are most interesting. The statistical review of their cases gives the youngest patient as seven years of age, the oldest as seventy-nine. The greatest incidence was found during the period of active reproductive power, an average age of thirty-three representing the midpoint of distribution. Sixty-five per cent were found between the ages of fifteen and forty; whereas in the menopausal group of from forty to fifty years, only 16.7 per cent were found, contrary to the usual belief. Eighty-three per cent were married; 14.6 per cent were unmarried; 2.3 per cent were widowed. The condition was most frequent in second marriages, particularly if the first had been a sterile union. Only 37 per cent had had previous pregnancies, and some of them had had many pregnancies. No particular race, creed or group was implicated. Included in the cases are the names of Mary Tudor, Queen of England, the wife of a French president, and a queen of Serbia. Only one case in a Negress was reported.

The more recent writers believe that this problem is more frequent in the emotionally unstable group. A few of Bivin and Klinger's cases went on to frank mental degeneration, but the majority were reasonably normal. The grim incredulity with which the true diagnosis is resisted is pointed

out as proof of an underlying psychogenic defect. The tenacity with which these patients go from doctor to doctor hoping for an encouraging diagnosis, the enthusiasm with which they prepare the *impedimenta* for their hopes, and the scorn in which they hold the luckless physician who pronounces the adverse opinion, are characteristic. Reports are given of three patients who persisted in their belief for eight, nine and eighteen years. However, the confidence of the large majority is shaken severely when the supposed gestation is prolonged over the tenth or eleventh month.

About 25 patients went through a normal pregnancy after having gone through a period of false pregnancy. Other cases in which interrupted pregnancies were continued as false pregnancies are noted. A few cases of multiple false pregnancies were reviewed; one patient had four, only to follow them with a fifth normal gestation. Several cases of pseudocyesis were overlooked because the examining physician could not exclude immediately an ectopic gestation. An embarrassing few have gone from a supposed pregnancy to a real one.

The main psychologic factors involved in these cases were desire, fear, hysteria, suggestion and autosuggestion. No one factor was present in all patients.

SYMPTOMS

It is now generally agreed that the patient need not have experienced a previous pregnancy for this diagnosis to be considered seriously. Only 37 per cent had had previous pregnancies in Bivin and Klinger's¹ series. The symptom-complex of pseudocyesis mimics in great detail true pregnancy.

In their review of the symptoms encountered in these cases, Bivin and Klinger found menstrual disturbance, particularly amenorrhea, the most frequently recorded symptom. This is statistically no more frequent than that in any age group. The amenorrhea, fatty deposition and constipation of menopause are an often-repeated triad. Emotion, menopause and endocrine disturbance are cited in explanation.

Enlargement of the abdomen was next in frequency, usually simulating that commonly associated with true pregnancy. The rate of enlargement often follows that of normal gestation. Flatus, constipation, fatty deposits in omentum or abdominal wall, a full bladder, retention of urine, diaphragmatic spasm. (hysterical) and muscular contraction, are given as possible explanations. Breast changes, including secretion, change in the size and character of areola, pigmentation and fullness, are noted. DeLee²⁰ pointed out that the breast signs have no significance in old multiparas,

since the breasts are enlarged and often contain milk for years. One investigator blandly explained that because milk was dried up by the stresses of some emotions, it would be logical to assume that other emotions could encourage production. The physician usually has no basis for comparison, but one patient, an artist, supplied her physician with hand-painted pictures of the changes of her breasts as reflected in her dressing mirror. Multiparity, pituitary dysfunction and menopause are offered as explanations for these phenomena.

Gastrointestinal symptoms, such as nausea, capricious appetite, constipation and vomiting, are common complaints. Fetal movements are of interest, for observers are impressed by the fact that those which the patients report are of unusual vigor, usually out of proportion to the supposed stage of gestation. Misinterpretation of normal somatic sensations ordinarily disregarded is the commonest explanation of such symptoms. Fetal heart sounds are reported rarely, a phenomenon probably due to abnormal transmission of a disordered maternal pulse. The duration of pseudocyesis in the great majority of cases is nine months, although some go ten or eleven months before suspicion is raised. Already cited have been three cases prolonged to eight, nine and eighteen years respectively.

DIAGNOSIS

Pajot²¹ states, "There are no false pregnancies, there are only false diagnoses." In 161 cases of Bivin and Klinger's series, one or more physicians were deceived by the signs or symptoms of their patients. Barnes²² counseled watchful waiting for a month to see if the issue cleared—either by frank progress of gestation or by subsidence of the symptoms. He referred the matter to "Time, the great solver of mysteries." Certainly there is no doubt that an incorrect diagnosis is a powerful factor in convincing an uncertain patient, and an equally potent one in disconcerting her medical attendant. Failure of the physician to produce concrete evidence in the ninth month removes this question from the medical field.

Some writers believe that it is difficult to differentiate true from false pregnancy. Caution in any patient whose story and physical findings are at variance will diminish the possibility of many unfortunate errors. The physiologic changes found in the breasts, cervix, vagina and uterus are never faithfully copied from pregnancy, but are only mild changes in that direction. One important sign is universally emphasized: the umbilicus is not the pouting one of gestation, but is the depressed umbilicus of the nongravid state. This,

combined with the alleged astonishing vigor of the fetal movements, should arouse suspicion.

The biologic tests of pregnancy are obviously of value in questionable cases. Roentgenography, if gestation has progressed sufficiently, is of aid, although confusion may arise from calcification within a fibroid, bowel contents, and so forth. Final resort is made usually to examination under anesthesia. Steady pressure under anesthesia will reduce the abdominal distention, with release of diaphragmatic spasm, and the passage of flatus. Occasionally, as the patient recovers from anesthesia, the distention recurs. Simpson in his *Diseases of Women* (1871) recounts the case of a Scottish peasant woman in her thirteenth month of pseudogestation. She refused to be convinced that she was not pregnant. Simpson put the woman under anesthesia and called her sister, who felt the spine through the collapsed abdominal wall. As the patient recovered, the distention reappeared, and she awakened to find no change in either her condition or her convictions. Her sister quieted her, "Hauld your tongue, woman, you've nothing in your wame for I felt your backbone myself with my ain hand."

TREATMENT

Whatever method has been devised to meet best the individual problems of the case is effective. Present-day methods are aimed at relieving by psychotherapy the patient's conviction that she is pregnant. Many women, however, will not countenance the diagnosis, seeking further medical advice, and usually leaving the first consultant without either fee or thanks. Bivin and Klinger¹ listed other methods, including informing the patient of her true state (56 cases), the use of anesthetics (50 cases), drugs such as morphine, opium, emmenagogues, and tonics (47 cases), purgatives (22 cases), hypnosis suggestion (19 cases), baths, curettage, operation, massage-pressure, catheterization, placement of uterus and psychotherapy.

CASE REPORTS

The following are the clinical histories of the 7 cases of pseudocyesis that occurred in the Boston Lying-in Hospital from 1927 to 1940. Search through the records of the Free Hospital for Women in Brookline, Massachusetts, failed to bring forth any additional cases. It is admittedly not a rare condition, although only 444 cases were reported by Bivin and Klinger from the time of Hippocrates until 1937. This infrequent recording of the disease may be due to lack of interest in the last three decades, to better methods of diagnosis

in pregnancy or to a subtle change in the feminine vapours.

CASE 1. M. C. (No. 38192), a 31-year-old para V, had had three miscarriages. One year before entry, a cesarean section was performed at another hospital, and a dead baby extracted. Previous catamenia had been regular each month, but were scanty, lasting 3 days, with some dysmenorrhea. The last flow had begun on January 9, 1927. The patient was first seen in the clinic on July 18 with an expected confinement date calculated for October 16. The symptoms included morning nausea with occasional vomiting, epigastric fullness and pain, dizziness and a "pregnant feeling inside." She had felt fetal movements in March, when she would have been about two months pregnant by dates. She had begun to flow a small amount just before entry, and was firmly convinced that she was aborting.

Physical examination was essentially negative. The breasts were small, and without secretion. The uterus could not be felt abdominally, and the abdomen was flat. The fetal heart was not audible. On vaginal examination, the cervix was firm, closed and lacerated. The fundus was posterior and of normal size. Vaults were clear. The flow was menstrual in type.

Treatment consisted of informing the patient that she was not pregnant, that she might have miscarried, and that this was a scanty period after amenorrhea for six months. This information was not well received. The patient did not again visit the clinic.

CASE 2. S. R. (No. 41331), a 41-year-old para III, had previously had two normal full-term deliveries, the last 11 years before entry. Both children had died within the first year of life. The last period began on February 13, 1928, and by dates, confinement was expected November 20. The patient first presented herself on November 26, believing herself to be beyond term, with bleeding. She had noted amenorrhea, nausea in the early months and abdominal swelling that progressed with gestation, and she was convinced of her pregnancy. In the fourth month she thought that she felt fetal movements. On November 19, she had slight painless bleeding of two days' duration. On November 24, she had indefinite abdominal pains, mostly about the umbilicus, which she interpreted as labor pains, and which brought her in to the clinic six days beyond her expected date of confinement. Physical examination of the breasts was negative. The abdomen was very obese, and a mass rising 26 cm. above the symphysis was noted, although it was poorly demarcated. The fetal heart was not heard. The patient seemed to be having mild labor pains. Because of the story of bleeding she was not immediately examined vaginally. X-ray examination revealed no fetal bones. Examination under anesthesia confirmed the diagnosis of pseudocyesis, because the findings were those of an atrophic uterus. She was informed of her nonpregnant state. "Labor" ended spontaneously. She did not revisit the clinic.

CASE 3. I. S. (No. 5625), a 44-year-old para V, had had four previous miscarriages at 3 to 4 months, the last occurring 1 year before entry. Catamenia were essentially normal until February 17, 1931, when she lost "two quarts of blood." She had no further flow until July 18. Over this period of amenorrhea, she noted abdominal enlargement, and was confident that she was pregnant, the expected date being November 24. On July 18, she had a little bright staining, fainted and was brought to the

clinic because she thought that she was aborting. Physical examination of the breasts was negative. No fetal heart was heard. No definite distention or mass was made out, although she had a large panniculus. On pelvic examination the uterus was small and anterior, with a closed, firm cervix. There was a slight thickening in the left vault. X-ray study and an Aschheim-Zondek test were negative. It was not difficult to convince her that the menopause was starting in.

CASE 4 F F (No 18229), a 27 year old para IV, had had three full term deliveries, the last two years before entry to the clinic. Her last period began on May 14 1937 and confinement was expected February 21, 1938. She had noted 5 month amenorrhea and progressive abdominal enlargement. In the 5th month she stained slightly and came to the clinic with a suspected miscarriage. Examination of the breasts was negative. Abdominal examination revealed the fundus at the height of a 5 months pregnancy. No fetal heart was audible. The patient was not examined vaginally for 6 days or until bleeding had stopped. At this time, the fundus was found to be only slightly enlarged, with a bluish, firm, hard cervix. The patient was observed for another month, with no change in the physical findings and with resumption of the normal menstrual cycle. Her conviction of pregnancy was considerably shaken by subsequent menstruation.

CASE 5 M D (No 3240), a 40 year-old para XIII, was first seen by the author in 1940, the patient was in bed at home, complaining of nausea, vomiting, lower abdominal cramps and bleeding, after amenorrhea of 7 months. She was convinced that she was 6 or 7 months pregnant. The breasts contained secretion, but the areolas were not typical of pregnancy. The abdomen was greatly scarred from three previous abdominal operations and palpation was difficult because of a large ventral hernia. One observer felt a diffuse mass rising to a height consistent with her presumptive confinement. No fetal heart was heard. On vaginal examination, the uterus was atrophic and fastened to one of the abdominal scars. The adnexa were normal. Bleeding was distinctly of menstrual character. When the author raised doubts as to pregnancy, the patient indignantly marshaled her family. She pointed to one child, saying, "That was a fibroid tumor at the — Hospital." Pointing to another, she said, "That was four negative A-Z tests at — Hospital." Indicating still another, she confounded the observer with, "That one was a negative A-Z test at your hospital!" Furthermore the patient volunteered that she had never felt fetal movements with any of her pregnancies, but only a wave, which had been present in this pregnancy, that she had never had any labor pains and that she had had regular cyclical menstruation throughout all her pregnancies. The difficulty of convincing her that she was not the victim of a similar medical plot on this occasion was indeed great. She was still not convinced, for she made subsequent visits to the hospital within a month after her flow stopped. There was no change in the physical findings.

On going into her history, however, it was found that none of the above statements could be verified, although in 1936 while she was under the care of a psychiatrist for treatment of a proved spurious pregnancy, she surreptitiously became pregnant and delivered about six months after the psychiatric cure had been effected. Study of hospital records of her previous prenatal courses and deliveries showed that she had had the usual amenorrhea of pregnancy, had felt fetal movement, and had delivered in pain despite her memories to the contrary. Her firm conviction

of pregnancy was perhaps a wisely tribute to her husband's powers.

CASE 6 A E (No 20910), a 29 year old para IV, entered the clinic on January 15, 1940, with a story that her last period had begun on November 13. She had felt swelling of the breasts and heaviness of the abdomen. The morning before entry she noted uterine cramps and flow commenced, facts which she believed to be due to a miscarriage, although no tissue was passed. Examination of nipples and breasts was negative. There was slight abdominal distention. The uterus was felt two fingerbreadths above the symphysis. She was treated for a threatened abortion for 1 week, when the bleeding stopped. It was thought that her flow might be menstrual. She again flowed on February 14, but this time without cramps.

She was followed in the clinic until April 29, at which time her gestation should have been at 5 months. The patient was firmly convinced of her pregnancy, had gained 7 pounds in weight, noted constant lower abdominal swelling, felt pregnant but had not observed fetal movements. Pelvic examination at this time showed a normal uterus, with no evidences of pregnancy. She persisted in her delusion, however, and was examined once again a month later to settle the matter. It may be that she did miscarry in the second month, but followed this with her spurious gestation.

CASE 7 H L (No 60739), a 26-year old para II, was first seen on May 11, 1940. This was in the seventh month of the patient's second marriage, and she desired a child very much. She had missed her February period, but had had flow each month thereafter, having just completed the period before her visit to the clinic. She had noted progressive abdominal enlargement, and her profile was that of a 5 month gestation. There had been a 20 pound gain in weight, swelling of the breasts, nausea, and vomiting usually at night. Both the patient and her husband had been greatly impressed with the vigor of the fetal movements when each nightly palpated the maternal belly.

Physical examination revealed nongravid areolas and breasts. There was no 5 month abdominal tumor. The umbilicus was depressed. The vaginal mucous membranes were not cyanotic. The uterus was firm and of normal size and consistence. Menstrual blood was issuing from the cervix.

She received the diagnosis of spurious pregnancy with contempt, and asked for laboratory confirmation. However, she consulted another physician, who concurred in the diagnosis. She ultimately capitulated.

SUMMARY

Pseudocyesis or spurious pregnancy is a clinical entity that has existed unchanged in its symptomatology since Hippocrates first described it. Explanations of etiology mirror the medical thought of each generation, from the old physiologic explanation of "wind in the womb" to the newer concept that places the syndrome on a psychogenic basis. The only additional aids to diagnosis have been the employment of roentgenography and of the biologic tests of pregnancy. Neither of these supersedes caution on the part of the physician in diagnosing pregnancy. Today's treatment is identical with that of our medical forebears, except that it is garnished with psychotherapy.

Seven cases are presented in detail from the records of the Boston Lying-in Hospital covering the years 1927 to 1940.

THE MANAGEMENT OF PRE-ECLAMPSIA*

FRED L. ADAIR, M.D.†

CHICAGO

IN DISCUSSING the management of pre-eclampsia, it is essential to reach some common understanding relative to a definition of the so-called "toxemias of pregnancy." In October, 1937, at the suggestion of Dr. Foster Kellogg, of Boston, a committee was appointed by the American Committee on Maternal Welfare to attempt to secure a uniform classification of the toxemias of pregnancy. This committee has reached a tentative classification, which may be modified more or less as time goes on. According to the committee's report,¹ the main headings consist of: hypertensive disease; renal disease; pre-eclampsia, mild; pre-eclampsia, severe; eclampsia; vomiting of pregnancy; and unclassified toxemia. These are covered in the following outline:

A. Disease not peculiar to pregnancy

I. Hypertensive disease (hypertensive cardiovascular disease)

- a. Benign (essential), mild, severe
- b. Malignant

II. Renal disease

- a. Chronic vascular nephritis or nephrosclerosis
- b. Glomerulonephritis
 - (1) Acute
 - (2) Chronic

c. Nephrosis

- (1) Acute
- (2) Chronic

d. Other forms of severe renal disease

B. Disease dependent on or peculiar to pregnancy

I. Pre-eclampsia

- a. Mild
- b. Severe

II. Eclampsia

- a. Convulsive
- b. Nonconvulsive (that is, coma with findings at necropsy typical of eclampsia)

C. Vomiting of pregnancy

D. Unclassified toxemias

I shall not discuss the management of any of these conditions except those falling under pre-eclampsia. Concerning this condition, the report contains the following remarks:

Pre-eclampsia, mild. Mild pre-eclampsia is the term applied to that condition which may or may not arise during pregnancy, almost always after the twenty-fourth week, characterized by a moderate rise of the systolic blood pressure to about 140 to 160 mm. of mercury and a diastolic blood pressure of 90 to 100 mm. of mercury. The urine contains less than 0.6 gm. of albumin per 100 cc., and the edema is usually slight and rarely may be absent. Usually no changes are demonstrable in the retinal arteries. Many of these patients have a latent hypertensive tendency. Few of them experience the severe pre-eclampsia, and fewer still have eclamptic convulsions. However, there are as yet no

*Presented at the New England Postgraduate Assembly, Cambridge, Massachusetts, November 13, 1940.

†Chairman, Department of Obstetrics and Gynecology, and Mary Campbell Ryerson Professor of Obstetrics and Gynecology, University of Chicago; chief of service, Chicago Lying-in Hospital.

certain clinical or laboratory methods of determining the potentially eclamptic cases among the patients with mild pre-eclampsia

Pre-eclampsia severe A condition which usually becomes evident after the twenty-fourth week of pregnancy, is characterized by a sustained systolic blood pressure of more than 160 mm of mercury and usually a diastolic blood pressure of more than 110 mm of mercury. Usually accompanied by the passage of more than 0.6 gm of albumin per 100 cc of urine. The edema is severe in most cases and usually hypertensive changes may be observed in the retinal arteries. In spite of the treatment there is a tendency for the blood pressure to rise, even when the edema may have decreased. Many patients present one or more of the symptoms of impending eclampsia, such as headaches, blurred vision, epigastric pain, vomiting, torpor or irritability.

Eclampsia is probably the same disease as severe pre-eclampsia, but in addition is accompanied by convulsions. Rarely, patients with severe pre-eclampsia who die in coma without convulsions show findings at necropsy identical with those of eclampsia.

In the textbook² of obstetrics and gynecology that was published under my editorship, toxemias of pregnancy were classified as follows:

- I Nonconvulsive toxemia of pregnancy
 - A Acute (pre-eclampsia) (46 per cent)
 - B Chronic (vascular renal disease) (48 per cent)
- II Convulsive toxemia of pregnancy (6 per cent)
 - A Acute (eclampsia)
 - B Chronic (uremia)

Under the heading "Nonconvulsive Toxemia of Pregnancy," the following statements are made:

This group comprising from 75 to 95 per cent of all toxemias, is composed of those who have edema, hypertension or albuminuria during pregnancy, labor or the immediate puerperium. It includes patients in whom these symptoms develop during pregnancy and also a large group of patients in whom these symptoms and findings become marked during the pregnancy. If the patient has been previously under observation, it is possible to know whether the toxemia is acute or chronic, but if not, then it may be possible to determine this from the history and findings.

Under the heading, "Pre-eclampsia or Acute Nonconvulsive Toxemia of Pregnancy," it is stated:

This disease differs from eclampsia in that neither convulsions nor coma occur. The mild type is variously designated as the kidney nephrosis, albuminuria or edema (hydrops gravidarum) of pregnancy, and there are, as a rule, few subjective symptoms. The severe type—eclampsismus or eclampsism—implies that the patient has marked subjective symptoms, and is on the verge of convulsions or of coma.

The typical case usually shows an excessive or rapid increase in weight. If the urines are obtained under standard conditions and sufficiently sensitive tests are used, an albuminuria will probably be found fairly

early, perhaps before the change in weight is apparent. The blood pressure begins to rise, and since an increase from a systolic of 90 to one of 125 is just as significant as an increase from 125 to 155, it is important to know the basic pressure. The maximal normal systolic blood pressure is arbitrarily placed at 129 mm. If the patient is over thirty, some allowance must be made for her age. Practically all patients with pre-eclampsia begin as mild cases and the condition may remain stationary or progress slowly. Usually, however, the signs increase, and as the condition grows worse, further subjective symptoms appear which indicate that it is likely to change from the nonconvulsive to the convulsive or eclamptic type.

The patient may have one, two or the whole triad of symptoms of nonconvulsive toxemia in varying degrees. Thus, one patient may have only a marked edema, another an albuminuria and a third perhaps only a hypertension. If increased blood pressure is the only finding, the condition is probably one of essential hypertension.

One has to recognize that a clear-cut distinction between these different conditions is often extremely difficult. The symptoms are not characteristic, nor are the findings pathognomonic for any one condition. There is overlapping between the various groups. The mild type may pass into the severe, and the severe may pass into the eclamptic. There is also confusion and difficulty in differentiating hypertensive disease, pre-eclampsia, and the acute and the chronic conditions. About the only way that this can be done satisfactorily is by following the patient not only throughout the course of the pregnancy but also during the subsequent post partum period for a number of months or even of years. It is often of help to know the antecedent history of the patient, and frequently, if it is possible, it is extremely helpful to know what the status of the patient was prior to the existing pregnancy. Often the history of the course of events in preceding pregnancies is helpful in making the diagnosis. Thus a patient can give a history of having had antecedent renal or vascular diseases either in the non-pregnant or in the pregnant state, this helps differentiate pre-eclampsia from eclampsia and other forms of so-called "toxemia of pregnancy."

Stander³ in a recent article approves the classification adopted by the American Committee on Maternal Welfare and accepts Kellogg's term, "mild pre-eclampsia," as a substitute for the designation, "low reserve kidney," proposed by him earlier. His criteria were hypertension of less than 150 systolic, 90 diastolic, which resumes the normal level after the puerperium, and albuminuria of less than 2 gm per liter, which rapidly disappears in the post partum period. There is nothing abnormal in the clinical constituents of the blood or urine, and subsequent pregnancies are

usually free of this condition. Stander gives the incidence of mild pre-eclampsia as 47 per cent, severe pre-eclampsia as 7 per cent, and eclampsia as 4 per cent in 104 toxemias occurring in 1503 pregnancies. Stander³ and Dieckmann and Brown⁴ found toxemia in as high as 10 per cent of pregnancies, about half of which fell in the pre-eclamptic group.

Evidence points to the fundamental identity of mild and severe pre-eclampsia with eclampsia. The major difference is in the intensity of the symptoms and findings. The onset of the convulsion or coma places the patient in the eclamptic group, unless these are caused by kidney disease resulting in uremia. No specific symptom or sign places these patients in the pre-eclamptic group. One must evaluate these cases from the available history and findings and decide whether they fall into the pre-eclamptic, the hypertensive or the vascular-renal group. The criterion that places them in the category of pre-eclampsia is a history of freedom from symptoms prior to or early in the pregnancy or in previous pregnancies.

The following findings are of diagnostic significance. Edema and weight gain are important when they are rapid or excessive. A definite but moderate gain in weight within a few days means more than a greater gain over a longer period. The normal patient may gain 20 to 25 pounds during pregnancy, but one whose weight has increased 2 or 3 pounds in a few days or a week should be regarded with great suspicion. Urinary findings of persistent albuminuria and increased number of formed elements are significant. A rapid or slow increase of blood pressure after the twenty-fourth week is indicative of pre-eclampsia. It is the increase that is significant. The rise of systolic pressure from 90 to 130 is just as important as one from 110 to 150. Insufficient attention is paid to the diastolic pressure, which is less variable than the systolic. The cerebral, visual and gastrointestinal symptoms are the danger signals showing the beginning of a severe toxemia. Urinary output in a diminishing quantity suggests strongly a disturbed water metabolism or impaired kidney function in the presence of a normal intake.

One may state that there is no specific treatment for pre-eclampsia unless the termination of pregnancy can be so regarded. If one were in a position to disregard the fetus, this would be the indicated procedure, which has two main objections: one is that no pregnancy resulting in fetal loss has been worth while; the other is that the artificial termination of pregnancy carries a danger to the mother and to the fetus alike. In the management of these patients, one is confronted with the problem of safeguarding two beings, the mother and the fetus, whose best interests are frequently

in conflict. That which is safer for the one may carry danger to the other.

In the management of the toxemias of pregnancy, there are two main viewpoints. First, one must consider the management of pregnancy, and secondly, it is necessary to treat the toxemic state. So far as the management of the pregnancy is concerned, I believe I should discuss my attitude toward the prevention of the pre-eclampsia. Since one cannot foresee the development of pre-eclampsia in a woman who has never been pregnant, this problem is present only in those patients who have had a previous pre-eclampsia or eclampsia.

There are no clear-cut criteria by which these various conditions can be differentiated, because hypertensive disease may first reveal itself during pregnancy, and because vascular-renal disease may also first be discovered during pregnancy. Another factor of importance is that the pre-eclampsia or eclampsia may so damage the cardiovascular-renal system of the patient that she does not subsequently recover. The amount of permanent damage done to the organs has not yet been determined, since there are no adequate criteria for judging the amount of anatomic or physiologic injury. I am of the opinion that the duration and the severity of the disease in a pregnant woman are the determining factors, and that a protracted course, even though apparently mild, does more damage than a severer but shorter attack of pre-eclampsia or even of eclampsia.

Attempts have been made to follow the patients during subsequent months and years, and there is no doubt that they have less subsequent interference with the functional capacity of their organs than those who have hypertensive or vascular-renal disease. However, I know of no study that has satisfactorily correlated the duration and severity of pre-eclampsia and eclampsia with subsequent events. One must remember that in pre-eclampsia one is dealing with an acute condition that may or may not lead to full recovery. In hypertensive and vascular-renal disease, one is confronted with an established disorder, which may be alleviated and arrested but cannot be cured.

Obstetricians are frequently handicapped by the fact that they have to rely almost entirely on the patient's history of the course of events in a previous pregnancy. If the patient gives a history of a previous toxemia, one should first attempt to establish the integrity of her organs. Before again becoming pregnant, she should be in good general health and free of symptoms of cardiovascular-renal disease, that is, the blood pressure, renal function and eye grounds should be normal. Very simple renal functional tests are total output and

ability to concentrate the urine; a uric clearance test may be done. It is difficult to know whether persistent changes of this character have been caused by some pre-existing disease, such as hypertension or vascular-renal disorders, or whether they have resulted from a pre-eclamptic or eclamptic attack, nevertheless, so far as future pregnancies are concerned, unless these conditions can be cleared no subsequent pregnancies should be permitted, because all of them are aggravated by a subsequent pregnancy. It should, however, be recognized that pre-eclampsia and eclamptic conditions are less apt to be followed by permanent damage than the vascular-renal disorders, which once established are apt to be persistent.

One must also consider the proper attitude toward a condition of this kind that manifests itself early in pregnancy. It is only in exceptional cases that pre-eclampsia appears before six months gestation, so that the question of the termination of the pregnancy rarely arises before that period. When any of these signs and symptoms occur prior to that time, the weight of evidence favors either hypertensive or vascular-renal disease rather than a pre-eclamptic state. Any progressive condition of this sort that develops early in pregnancy should lead to the termination of the gestation, otherwise the mother's condition is aggravated, she is apt to suffer permanent damage, and the chances for securing the survival of a viable fetus are not good. There is also the threat of ante-partum fetal death, especially in the vascular renal type of the disease.

The objectives of management are to prevent maternal and fetal deaths and to avoid serious or permanent damage to the tissues and organs of the mother. To state the problem in different words, every effort should be made to protect the health of the mother and to secure a viable, living fetus. This fetus should be sufficiently mature to have a reasonable chance of surviving the neonatal period. To protect the mother, one must detect the condition early, watch its course closely and manage it from the interest of both the mother and the fetus. It must be remembered that no prospective mother is completely satisfied, at least psychologically, unless she has a living baby. One must never forget that although many women do not have a recurrence of this condition in a subsequent pregnancy, nevertheless, all things considered, the existing pregnancy is the most favorable one for securing a living baby. There are no absolute criteria for determining the best course to follow for either the mother or the fetus. The final decision rests on mature judgment derived from the careful evaluation of the symptoms and findings and the progress of the disease. There is no specific treat-

ment for this condition. The management is, therefore, largely symptomatic and consists mainly of watchful expectancy under the most favorable possible conditions, for the mild case may become severe, and the severe may become eclampsia. Because the rate of progress is by no means uniform, one must watch the course of events very carefully. A mild pre-eclampsia, or even a severe one, may never develop into an eclampsia. On the other hand, a fulminating eclampsia may develop with relatively scant evidence of a transient pre-eclampsia. It is interesting to note that whereas the incidence of eclampsia has been reduced, there has been no evidence to prove that pre-eclampsia has diminished. One must therefore conclude that in all probability the eclampsia was the result of the neglect of the pre-eclamptic condition. There is little evidence that the dietary and other management of pregnancy has reduced the incidence of the condition, although it is quite possible, in fact probable, that its severity has been ameliorated by proper ante-partum management. There is no specific preventive treatment for pre-eclampsia. One should endeavor, however, to maintain the patient in the best possible physical state by securing optimal nutrition and hygiene throughout the course of the pregnancy. She should receive proper nutrition, adequate rest and recreation and should have good elimination, in other words, normal health habits. It would, of course, be better to have the patient in the best physical condition before pregnancy occurred. After conception, every effort should be devoted to relieving symptoms, such as nausea and vomiting, and to correcting nutritional abuses and faulty habits of living. Even though one is unable to prevent the development of a pre-eclampsia, the patient would be in better physical condition to withstand the development of this disease.

The important triad of symptoms and signs are increase in blood pressure; development of edema shown either by soggy skin or pitting of the tissues and by rapid increase in weight; and development of an albuminuria.

When any of the symptoms or signs of pre-eclampsia develop, a more rigid regime should be instituted and should vary with the severity of the signs and symptoms. The diet should be restricted, and should consist, so far as possible, of fruits and vegetables with a moderate amount of protein—in other words, a maintenance protein intake. A salt poor or salt free diet should be given. The fat should also be restricted; preferably no fat other than milk fat should be used. Lean meats and eggs may be used. No fried foods or pastries should be given. Fish, pork and veal should be eliminated from the diet. The protein

intake should be about 60 gm., with approximately 30 gm. of fat and 400 gm. of carbohydrate, a total of about 2100 calories a day. Fresh vegetables may be used in the form of salads, but oil dressings should be omitted. In severe cases, the diet may be further restricted for a week to fruit juices with sugar and possibly some skimmed milk—about 1200 to 1500 calories. In mild cases, rest at night of eight hours, with one or two hourly periods of rest during the day, may be sufficient. Sedation may be required to secure adequate sleep, the barbiturates being preferable. Urinary output should be watched, and gastrointestinal elimination should be secured. When the patient is placed at bedrest, an apparent disappearance of the edema should not be confused with a shift in the edema to the dependent portions of the body. In the severer cases in which there is marked edema or anuria, the fluid intake and output should be closely watched, and if necessary intravenous injection of 10 to 20 per cent glucose should be utilized to promote diuresis. If the patient fails to respond favorably to this treatment of rest, diet and elimination with sedation, it is necessary to decide promptly whether to terminate the pregnancy.

If the condition remains stationary so far as the symptoms and signs indicate, more time may be allowed for reaching a decision. One good rule to follow is that when there is nothing to gain for the fetus, the health and life of the mother should not be imperiled by delaying the termination of the pregnancy. In the pre-eclamptic state, there is little danger of ante-partum death of the fetus. The main causes contributing to the fatalities of the fetus and the newborn are mechanical induction of labor, artificial termination of labor other than cesarean section, and previable or early premature births. The outlook for the fetus is always better if the onset of labor is natural and its termination is without unnecessary interference. There is little evidence that low-forceps operation or delivery by cesarean section is an increased hazard to the fetus, although it may be to the mother.

The period of gestation at which hypertension, edema and albuminuria with visual and other symptoms develop naturally determines somewhat the course to be pursued. If these symptoms develop before the twenty-fourth week of gestation, there is little to be accomplished by delay unless they disappear very rapidly under appropriate treatment. If they appear after the twenty-fourth week in a severe form with no response to treatment within a week, the pregnancy should be terminated; if in a mild form, expectant treatment may be used. If the mild condition is progressive, pregnancy should also be terminated after a

week or ten days of adequate treatment without improvement. In a patient with a progressive pre-eclampsia, either mild or severe, that occurs earlier than two weeks prior to fetal viability, expectant treatment is contraindicated, especially in those cases in which there is no improvement within a week of adequate treatment. In pre-eclamptic patients in whom the fetus is dead or previable, the termination should always be from below. It usually requires some mechanical form of induction, such as rupture of the membranes, the use of a bag or Willett's forceps, or vaginal hysterotomy. When the fetus is previable or dead, destructive operations are not necessarily contraindicated.

When the pregnancy has reached a period verging on fetal viability, the problem is often complicated and difficult to answer. An attempt to prolong the gestation in the interest of the fetus should be made if it can be done without imperiling the health and life of the mother. When the pregnancy has reached term, there is little to gain for the mother by prolonging the gestation, and every effort should be made to have the pregnancy terminated prior to the development of a severe pre-eclampsia or an eclampsia that materially increases the hazard for both the mother and the fetus, because under those circumstances one has to deal with an emergency situation. The best outlook for both mother and baby is obtained when there is a natural onset of labor with as nearly natural a termination as possible. If it is possible to prolong the gestation until the cervix is soft, a medical induction with castor oil and quinine may be sufficient to initiate labor. Pituitary extract for the induction of labor should be used with extreme caution in toxic patients. A second attempt at medical induction may be made when the first one fails. There usually should be an interval of at least a day between attempts at medical induction. Mechanical induction consists in simple rupture of the membranes, the introduction of a bougie or bag or the use of Willett's forceps, which is not advised except in cases of previable or dead fetuses. Braxton-Hicks version may also be tried, but it is a dangerous procedure so far as the fetus is concerned and should not be employed except in cases of previable or dead fetuses. When the cervix is not soft, mechanical induction of labor is accompanied by a very high fetal mortality and some risk to the mother. Every effort should be made to carry the mother to the period when the cervix is soft so that the medical induction has a fair chance of being successful. When the necessity for terminating the pregnancy is urgent and the cervix hard, one is confronted with the serious problem

of deciding between the mechanical induction of labor with danger to the fetus or the possibility of doing a cesarean section with relative safety to the fetus. The latter should be done only in those cases in which the outlook for the fetus is excellent and in which the environmental conditions are such that it can be done with great safety to the mother.

Many other factors, such as age, parity, fertility, personnel and environment, have more or less weight in determining the final decision. These patients can be best cared for only by adequate preconceptional, ante-partum, intra-partum and post-partum care in the office, the home and the hospital. The danger to the mother entails risk to

the fetus, which arises not from the toxic state itself but from the procedures used to terminate the pregnancy. The management of toxemias should be designed to preserve the health and lives of both the mother and the fetus and should consist in the judicious use of medical and obstetric procedures at the proper time and place and in the approved manner.

MEDICAL PROGRESS

ETIOLOGY AND TREATMENT OF URTICARIA: DIAGNOSIS, PREVENTION AND TREATMENT OF POISON-IVY DERMATITIS

PERRY C. BAIRD, JR.*

BOSTON

URTICARIA

URTICARIA should be thought of not as a disease manifesting itself solely in the skin but as a process capable of involving many other structures and organs of the body. Typical urticarial wheals have been demonstrated in the stomach by gastroscopic examination. Involvement of the throat or larynx is not rare and creates an emergency situation in some cases. Apparently, urticarial swellings may occur wherever loose connective tissues exist. On the basis of these considerations, it would be possible, on theoretical grounds, to account for a number of disorders as manifestations of an internal type of urticaria. For example, urticaria might extend to the lungs producing a form of pulmonary edema, to the heart producing paroxysmal tachycardia, to the brain causing headaches, to the bladder creating hematuria, and to the urethra causing anuria.

Urticarial wheals, therefore, represent an important study in pathologic physiology, and the mechanism of wheal formation deserves close scrutiny. Of great interest and importance is the fact that wheals can be produced experimentally by an immunologic technic that represents a probable reproduction of the actual disease process. This

method of wheal production may be described as follows. A small amount of blood serum (0.01 to 0.05 cc.) removed from a food-sensitive patient is injected intracutaneously into a subject. After the passage of twenty-four to forty-eight hours, the subject is fed a definite amount of the specific offending food to which he has been locally sensitized. From two to ninety minutes after ingestion of the food, a reaction consisting of a wheal surrounded by erythema and accompanied by pruritus appears at the passively sensitized site. This interesting procedure has been described and studied with great care by Walzer and Walzer.¹ It corresponds to the Prausnitz and Küstner test of local passive transference of hypersensitivity.

Straus² has reported that the rhesus monkey will accept passive transference of local skin hypersensitivity from human reaginic serums. This fact is of absorbing interest and may prove to be of great value in the experimental study of urticaria and allied skin disease. In this same connection, Sherman, Stull and Hampton³ have discovered that the serum of guinea pigs sensitized by injection of pollen toxoid contains a substance that will produce passive transitory sensitization of the human skin. In the study of urticaria, therefore, it is now possible to make experimental use of the rhesus monkey and the guinea pig.

*Associate in dermatology, Peter Bent Brigham Hospital

The question of whether or not the wheal reaction actually represents a form of allergy has been a source of much discussion. It seems true, as indicated by Sulzberger and Goodman,⁴ that some types of urticaria are definitely not allergic. These authors point out that "primarily urticariogenic agents such as morphine, codeine, atropine, pilocarpine, histamine and choline" do not produce urticaria of a clear-cut allergic type. Blum and West⁵ studied a case of urticaria due to blue and violet light. They investigated the wave lengths of these colors, as well as other angles of the problem, and concluded that the true cause was carotenoid pigment rather than any conceivable type of allergy. In Urbach's⁶ review of 500 cases of urticaria, he noted that only 20 per cent could be interpreted as forms of allergy. Winkelwerder⁷ has written a thesis concerning the relation between urticaria and angioneurotic edema, and has concluded that both urticaria and angioneurotic edema are symptoms of an underlying physiologic disturbance, not necessarily an allergy.

The allergic types of urticaria and angioneurotic edema are common and represent in all probability a true antigen-antibody relation in cases of pollen sensitivity, serum disease and foreign-protein reactions. It must be pointed out again, however, that in urticaria due to drugs no one has been able to demonstrate a true antigen-antibody relation. Nevertheless, recent investigations have shown that simple chemicals when combined with proteins take on the characteristics of true antigens. In such cases, the specificity of sensitization to the chemical protein conjugate depends on the simple chemical attached and not on the protein. It is possible that urticaria-producing drugs, such as aspirin, may combine with body proteins and become allergenic.

Urticaria is a disease of great prevalence, and the usual case is so easily diagnosed that most patients know what ails them before consulting the physician. It is probable that few people pass through life without having an attack of hives. The attacks are often mild and of short duration, and spontaneous disappearance may take place in a few hours, before the necessity of consulting a physician becomes apparent. Many other cases, however, present the most resistant and baffling dermatologic problems. It is likely that a considerable percentage of all patients, including the resistant ones, do not consult specialists but rely on general practitioners for treatment of their difficulties.

On the basis of clinical experience, it is natural to divide urticaria into acute and chronic types. The acute form usually runs a brief course, lasting from a few days to two or three weeks, and terminates, as a rule, in complete recovery. Al-

though the symptoms of acute urticaria may be relieved and the duration of the disease may be shortened materially by proper treatment, the attack will subside spontaneously without any treatment whatsoever. The evaluation of treatment of urticaria is difficult, but it is particularly hazardous in acute urticaria. The value of therapy can be determined more safely in the study of the chronic type of cases that have lasted for months or years.

There seems to be fairly general agreement that skin tests in urticaria are of decidedly limited value and are to be recommended not as a routine plan of study but as a last resort in stubborn cases. As Ormsby⁸ puts it, "In hives, skin tests are often positive to substances that are innocent and negative to substances that are causal." As pointed out by Traut,⁹ the urticarial reaction differs from true allergy in not being mediated by the reagin mechanism, and in the absence of reagins, cutaneous tests usually give negative results. On the other hand, false reactions are to be expected quite commonly on the basis of the dermatographia usually present in association with urticaria.

In the search for the etiology of acute urticarial recurrences, the patient's own observations regarding causative agents are of the greatest value. Intelligent patients will usually make observations of considerable interest and importance, particularly if there have been regular attacks caused by specific foods or drugs. With patients who have not become fully aware of the eliciting agents in their attacks of hives, well-focused history taking may establish a demonstrable chronologic sequence between ingestion of specific substances and the appearance of attacks. If a careful history fails to give a clue, the elimination diet (Rowe¹⁰) or a dietary diary may be employed. In this type of investigation it is of value to bear in mind the list of foods and drugs which are likely to cause hives. Frequent causes are the following (Wise and Sulzberger¹¹):

FOODS	DRUGS
Shell Fish	Quinine
Fish (including caviar)	Ipecac
Strawberries	Salicylates
Cheese	Barbiturates
Nuts	Iodides
Eggs	Bromides
Wheat	Phenolphthalein
Milk	Morphine
Pork	Other opium derivatives
Chocolate	Antipyrine

These two lists will account for the majority of cases of acute urticarias, but it must be remembered that no food or drug can be said to be incapable of producing urticaria.

Certain pitfalls may be encountered in the study of urticaria. These may be enumerated as follows¹²:

A certain food may elicit a severe attack at one time but not at another (sensitive and nonsensitive phases).

A food such as fish or dried fish, if fresh, may fail to produce hives—but if not absolutely fresh will cause an attack.

Vegetables and fruit grown in one region may cause hives, whereas the same vegetables and fruit grown in another region may fail to do so.

Certain combinations of foods may be followed regularly by an eruption—whereas these foods individually may be without harmful effect.

The time between ingestion of food and eruption may vary between minutes to hours or days.

Following a single exposure to a sensitizing substance, urticaria may last varying lengths of time—from a few hours to many weeks. Drug eruptions often last for long periods of time.

Urticaria may be produced by inhalation of the following substances¹³: feathers, orris powder, animal danders, pollens, ephedrine and other nasal sprays, and various dusts, such as house, silk, cotton and kapok.

In the management of cases suspected of being of inhalant origin, the patient's rooms, especially the bedroom, should be made as dust free as possible; furnishings stuffed with feathers, kapok or cotton, especially pillows and mattresses, should be removed or covered with so-called "allergen-proof" materials. The patient as well as the friends and relatives in his immediate environment should be forbidden the use of all cosmetics and toilet preparations except those of nonallergic nature.

Localized hives may be produced by contact allergens such as the following: silk, wool, dyes, cosmetic preparations, flour, fur, fur dyes, eggs, rose-perfumed bath salts and lemon peel. Allergens such as these, acting externally, are capable of producing not only localized urticaria, but also vesicular contact dermatoses. Furthermore, by absorption through the skin, they can produce generalized urticaria. It is interesting to ponder that the skin of one patient will react to an agent such as wool with vesicle formation, whereas the skin of another will respond to wool only with wheal formation.

In the study of chronic urticaria it may well be borne in mind that discovery of the cause is usually far more difficult and less likely than in acute urticaria. Well-directed investigation of cases of chronic urticaria should include a careful survey of possible food factors and inhalants, close attention to drugs and search for foci of infection.

In the management of chronic urticaria, all drugs previously administered should be discontinued at the outset of study and therapy. The most frequent offenders include morphine, salicylates, barbiturates and laxatives. The following

potentially causative agents should be inquired for in the carefully focused history¹⁴: laxatives, sedatives, soporifics, tonics, douches, contraceptives, nasal sprays, eye drops, mouth washes, tooth powders, tooth pastes, hair dyes, scalp lotions and iodized salt.

A patient with chronic urticaria using any of the agents mentioned above should discontinue them for at least six weeks. In addition, if the case is stubborn, it is well to exclude as rigidly as possible feather-stuffed furniture and bedding, and cosmetics containing dyes or perfumes. Nonallergic cosmetics should be prescribed for the patient, as well as those in intimate contact with the patient.

Foci of infection represent a common cause of chronic urticaria, in fact one of the most prevalent. Apparently, teeth represent the commonest focus. Dramatic cures of chronic urticaria have been reported following removal of nonvital teeth in which the apical infection was so slight that it could not be demonstrated by roentgenography.¹⁵

Nervous and emotional stress and strain can without any doubt elicit urticarial attacks. This aspect of urticaria has been studied in admirable fashion in this country by Stokes and his co-workers.¹⁶ His contributions to this field should merit careful reading by all interested in the problem of urticaria.

Of considerable interest in the literature of recent years are the unusual and unexpected etiologic agents that have come to light. A scrutiny of some of these agents should broaden the understanding of the etiology of urticaria, and should help one to deal with the many unsolved cases of chronic urticaria with which one is so often confronted. As one reflects on some of the bizarre cases that have been investigated successfully and reported, it becomes increasingly easier to comprehend why many such urticaria cases remain unsolved, even when studied in clinics operated by highly skilled workers and fully equipped with all modern laboratory apparatus. Those cases found to be due to foci of infection have seemed to be particularly difficult problems.

Many of these interesting cases of urticaria have proved to be due to simple causes, which have remained unidentified for months or years, in spite of the fact that in the end they seemed almost obvious and not deserving of so much diagnostic difficulty. For example, Rappaport¹⁷ studied a case of chronic urticaria in a dentist and found him sensitive to acrolein, formed by the oxidation of glycerin in cigarettes. The patient could smoke with impunity cigarettes containing no glycerin, but after a drop of glycerin had been placed on such a cigarette, an attack of hives would appear as

the cigarette was smoked. As one might well predict, this patient suffered from hives when eating steak broiled over a hot flame, or when eating broiled fish, owing to his absorption of acrolein formed by the oxidation of fat. (Acrolein is related to formaldehyde, and is a very active aldehyde produced in any food containing fat or prepared with fat if sufficient heat is produced, as in broiling or frying.)

One of my cases proved to be an interesting example of a type of urticaria found in the end to be due to a simple cause overlooked in spite of careful previous studies over a period of one and a half years. The history of the case was lengthy and difficult to analyze. It was found, however, that the patient's occupation involved contact with and handling of numerous dye chemicals. The patient himself had observed that inhalation of formalin vapor made his attacks worse. He had also noted that when away from the factory on vacations he had no difficulty. Physical examination showed numerous large urticarial wheals and violent dermatographism. While in my office, the patient consented to inhale some formalin fumes as a test. After an interval of about ten minutes he broke out with about a dozen additional urticarial wheals associated with extreme itching. Remembering that formalin vapor can be neutralized rapidly by spirits of ammonia, I had the patient moved to a second room and inhale spirits of ammonia. The itching disappeared instantly, but the hives remained unchanged. One would expect the edema of urticaria to be slow in absorption even after removal of the cause. After these tests and after explanations, the patient was able to recall that he could work without difficulty in the dye factories that did not use a formalin-fixation system. The skin tests were particularly interesting: A drop of formalin placed on the skin produced no reaction for an interval of about ten minutes until gross chemical irritation began to appear. A second drop of formalin, applied to the skin and followed by a tiny puncture, produced immediately a typical wheal, which was promptly reduced in size by application of spirits of ammonia. In other words, the horny layer of the skin in this case did not react to formalin except as a consequence of gross chemical irritation, but the blood vessels exposed by a tiny puncture responded to formalin promptly. The implications in regard to prevention and treatment of attacks in this case were obvious. The patient found that his itching could be taken care of very satisfactorily by carrying in his pocket a small bottle of spirits of ammonia and by inhaling the ammonia vapor when exposed to formalin vapor.

Waldbott and Ascher¹⁸ have studied and re-

ported 5 interesting cases of urticaria of the serum-sickness type. These cases all had a definite incubation period of five to nine days, and all were associated with fever and joint and glandular swellings. The clinical picture, therefore, was typical of serum sickness. In 4 of these cases, the condition was brought on by means other than injections, such as ingestion, contact and infection. There was one case of chronic urticaria of four years' duration. The attacks came every six weeks, lasted four or five days, and were each preceded by a flare-up of an old chronic dermatophytic infection of the feet. This case showed a prompt therapeutic response to local applications to the feet and the injection of autogenous fungous extracts. Wise and Sulzberger¹⁹⁻²⁰ believe "fungi of the trichophyton group to be definite but relatively infrequent causes of clinical urticaria." These investigations demonstrate that in studying cases of chronic urticaria one should always examine the feet and other areas of skin for evidence of dermatophytosis and weigh such evidence as a part of the problem. Perhaps some of the many unsolved cases will be found to be due to foci of fungous infections.

Another case studied by Waldbott and Ascher was that of a thirty-nine-year-old dentist. The clinical picture was that of a generalized severe form of urticaria and was found to be due to aspirin. After stopping aspirin the skin condition persisted eight days and then disappeared entirely. One grain of aspirin taken by mouth produced severe urticaria within ten minutes. Of considerable interest in reference to this case was the fact that the scratch and patch tests with acetylsalicylic acid were entirely negative.

Sulzberger, Goodman, Byrne and Mallozzi²¹ in their careful investigation of the subject of cheilitis due to lipstick, found 2 cases in which the cheilitis was associated with chronic urticaria. Both the cheilitis and chronic urticaria disappeared when exposure to the dye of the lipstick ceased—cheilitis due to lipstick is caused, in most cases, by the dye rather than by the perfume or other ingredients. In one case the patient deliberately applied her old type of lipstick again, and both cheilitis and generalized urticaria recurred. From these observations it may be said that lipstick represents one of the easily missed causes of urticaria.

An intensely interesting and important chapter in the knowledge of urticaria concerns the type caused by physical agents, with particular reference to heat. The subject has been much better understood since the work of Grant, Pearson and Comeau,²² reported in 1936 and reviewed in the paragraphs to follow. It is likely that many cases of urticaria provoked by heat fit into the chronic

resistant group and are often not recognized and treated properly.

The term "physical allergy" was described by Duke² in reference to a special group of conditions, which may be enumerated as follows: bronchial asthma, vasomotor rhinitis, conjunctivitis, photophobia, abdominal pain, erythema, pruritus, urticaria, and angioneurotic edema and shock. This list represents a group of symptoms that may be "caused specifically and solely by the action of a physical agent, such as light, heat, cold, mechanical irritation, freezing and burns, and, in the case of heat sensitivity, indirectly by mental and physical exertion."

Recent studies of the important subject of urticaria provoked by heat or by psychic stimuli have been carried out by Hopkins, Kesten and Hazel,³ who have also reviewed the literature in an illuminating manner.

Experiments have shown that generalized urticaria due to heat, physical exertion or emotional excitement is brought out by a highly interesting physiologic and biochemical mechanism. Grant, Pearson and Comeau²² have presented convincing evidence that the lesions are produced by release of acetylcholine at the termination of cutaneous nerves—the first demonstration of a mechanism by which a psychic stimulus can produce a definite lesion in the skin. These workers made the following observations:

If one leg of a patient with 'heat urticaria' is placed in hot water, a generalized outbreak of wheals will appear anywhere except on the heated skin. The leg becomes flushed but is usually without wheals. This indicates that the wheals are not produced by the direct effect of heat on the skin.

If before such a test the circulation of the leg is occluded by a cuff, no wheals appear until after the cuff is released and circulation restored. This indicates that the essential stimulus is transmitted from the heated skin by the blood and not by the nerves.

If in a similar experiment the circulation in one arm is occluded by a cuff, although no wheals appear while the arm is ischemic, 'numerous bluish spots of local vasodilation' can be seen. This indicates that the stimulus is carried to the area in which wheals develop by nerves and not by the blood. If at a suitable time the circulation is released and the capillary pressure restored, wheals immediately appear, usually in these spots of vasodilation.

Attacks of urticaria can be produced in these patients by acetylcholine.

These experiments with heat indicate that the urticaria in these cases was produced by a nerve impulse reaching the skin from some central heat-regulating center stimulated by the arrival of warmed blood from the extremity.

Both normal and heat-sensitive patients react

with dilatation of cutaneous blood vessels when one extremity is heated. They also show these reactions to emotional stimuli. In other words, an increase in body temperature or a purely psychic stimulus may excite the sweat gland nerves and the autonomic vasodilation fibers to secrete acetylcholine in normal subjects and in heat-sensitive patients. The essential abnormality of the latter is that acetylcholine produces wheals in their skin.

There seems at present no proof of the nature of the abnormal reaction to acetylcholine by these patients. One is tempted to assume that the patients are specifically allergic to this chemical, but there is as yet no evidence that allergy to acetylcholine can be produced. Hopkins and his associates²⁴ attempted passive transfer tests of sensitivity by means of the serum of heat urticaria patients, but the results were inconclusive. The evidence indicates, however, that whether the urticaria follows exposure to heat, exercise or nervous excitement, it is caused by a direct action of acetylcholine or some related biochemical substance on the cells of the skin.

Urticaria due to heat may be brought on by the effect of a warm room, standing in front of the fire, hot baths, exposure to direct sunshine on warm days, warm bed clothing, emotional excitement, violent exercise, hot food, anger or nervousness. This type of urticaria may be relieved temporarily by a cold shower. The lesions are apt to come out in susceptible subjects after the rectal temperature has risen 0.4 to 1.2°F. A very effective stimulus may be delivered by immersion of the feet in hot water.

One of Hopkins's patients with heat urticaria was successfully treated, with complete recovery, by increasing gradually the temperature of her daily bath.

The great importance of the acetylcholine reactions of the body has been brought out by the work of Hall, Ettinger and Banting,²⁵ who produced coronary and myocardial lesions and ulcers of the stomach and duodenum both by administration of acetylcholine and by stimulation of the vagus nerve.

Treatment

The circulating allergens that produce acute hives are, with scarcely any doubt, usually of alimentary origin. Therefore, the first step in etiologic therapy is to clean out the gastrointestinal tract, unless good evidence can be obtained of the possibility that there is some less common cause of acute urticaria, such as inhalants, foci of infection or contact allergens (absorbed by transepidermal penetration). For cleaning out the intestinal

tract, Wise and Sulzberger²⁶ recommend calomel in a dose of 3 to 6 gr. at night, followed in the morning by a saline cathartic. Daily morning doses of a saline cathartic may be continued for several days. The food should be bland and the intake limited. Fluids should be forced to aid elimination of allergens. Violent exercise should be avoided, because it increases the blood supply to the skin and increases the severity of symptoms. Alcohol should be avoided, because it tends to increase absorption of allergens from the gastrointestinal tract and also increases the blood supply to the skin.

Some of the newer methods of therapy in urticaria should be described. Many of these are based on physiologic mechanisms of clear-cut etiologic importance. Others are more empirical in nature. The evaluation of therapeutic measures used in treating urticaria is hazardous because it is impossible to anticipate the course of the disease in any particular case. Even severe cases of long duration may exhibit sudden and inexplicable spontaneous remissions. This fact probably accounts for the large number of remedies that have been advocated, and also explains why so many of these remedies have not stood the test of time.

In the therapy of urticaria at Northwestern University it was observed by Rosenberg²⁷ that the use of elimination diets sometimes was associated with exacerbation of the disease. This observation, coupled with the fact that some of the patients had been on relief and some had been on a prolonged diet containing limited amounts of citrus fruits and fresh vegetables, led to a consideration that vitamin C deficiency might be etiologically significant in these cases. Since urticaria is a disease involving the small blood vessels and since vitamin C deficiency is known to be capable of causing a defect in capillaries (Wolbach and Howe²⁸), it seemed logical to study the vitamin C content of the blood in these cases and to test the effect of therapy by means of vitamin C. It was found that the blood vitamin C level was reduced usually about 50 per cent below normal. Also, it was found that the administration of vitamin C in the form of lemon juice and orange juice produced a sharp rise in the blood vitamin C level and relieved wholly or in part the symptoms. The case histories reported are interesting.

Rusk and Kenamore²⁹ have reported a series of 6 cases of urticaria which were resistant to the customary forms of therapy, such as Rowe diets, elimination of foci of infection, and other routine measures. These cases were subsequently managed with surprisingly favorable results by means of a high-protein, low-sodium, acid-ash diet of average

caloric value with potassium chloride added in dosage of 60 to 90 gr. daily. Potassium was administered on the basis of its action as a depressant to skin irritability and of its other effects similar to the action of adrenalin. Cohen³⁰ used the Rusk and Kenamore treatment in 8 cases of urticaria, and none of these showed any improvement whatsoever. Such discrepancies in the results of various forms of therapy, as employed by different workers in different localities, are frequently encountered in all branches of medicine, as is well recognized. It is probable, however, that these discrepancies are particularly noticeable in the many forms of treatment advocated for urticaria.

After having used insulin successfully in certain cases of refractory eczema, Caven³¹ studied its action in 2 cases of severe urticaria. Favorable results were obtained. One patient was found to be sensitive to wheat, eggs and milk, and a restricted diet brought relief, but the slightest dietary indiscretion caused prompt recurrence. Daily injections of 5 units of protamine zinc insulin resulted in an improvement to the extent of permitting the patient to eat bread without distress, whereas previously one slice of bread had caused pain in the abdomen and swelling about the eyes within an hour or so. The second patient developed severe, acute generalized urticaria following a suprapubic cystotomy. The precise cause of this case of urticaria was not identified, and the usual types of treatment brought no relief. Three hours after the injection of 8 units of protamine zinc insulin, all signs of urticaria disappeared promptly. There was a mild recurrence several days later, but this was checked by another injection. After that no further occurrences were observed.

Hajos,³² in a study of chronic urticaria, found that among his patients the gastric hydrochloric acid was absent in 65 per cent and lowered in 30 per cent. Cholecystitis was often present among these patients. In treatment, he employed hydrochloric acid by mouth and histamine injections. Favorable results were obtained.

According to Freund,³³ the only means of relieving immediately the itching of urticaria consists in repeatedly rolling a very hot, uncovered water bottle over the involved area. Wise and Sulzberger³⁴ agree with this general viewpoint and state that the relief of intolerable crises of itching is often best accomplished by the application of heat, such as immersion of the part in water as hot as the skin will bear.

According to Hopkins,³⁵ one should think, in dealing with chronic urticaria, of bacterial sensitization as the likeliest cause, and of allergy to food as the least likely. In some of his cases of in-

tractable urticaria, Traut⁹ found hemolytic streptococci and green streptococci growing in abnormal profusion in the rectum. In the absence of other detectable causes, these patients were treated with vaccines of rectal streptococci, and the results were good. The patients treated successfully by this method had usually received prolonged and fruitless therapy along many of the usual standard lines, such as Rowe diets, avoidance of wool and silk, removal of husband, aunt, daughter and dog, and injections of whole blood and calcium. One patient with chronic urticaria of fourteen years' duration was treated by a series of seventeen injections of streptococcal vaccine and was relieved completely, having had no recurrences in two years at the time the case was reported. From the Mayo Clinic (Emmett and Logan³⁶) a case of chronic urticaria of seventeen years' duration has been reported; this patient was treated and cured by an autogenous vaccine of colonic organisms.

The bacterial origin of urticaria has been studied in an illuminating manner by Hansen-Prüss,³⁷ who has analyzed and reported several cases of great interest. One case of severe urticaria was found to be due to a pyelitis caused by a hemolytic *Staphylococcus aureus*, and cleared when the urine cultures became negative. There was a strong immediate skin reaction to staphylococcal toxoid, and this was found to persist two years after disappearance of the urinary infection. A second case of Hansen-Prüss's showed x-ray evidence of gall-bladder disease, and this led to bacteriologic studies of duodenal-drainage material, which proved to contain hemolytic streptococci. Stool cultures showed hemolytic colon bacilli and beta hemolytic streptococci. This case was treated successfully by Prontylin and Prontosil. The urticaria disappeared, and cultures of the stool and duodenal fluid became negative.

Hansen-Prüss succeeded in demonstrating the presence of beta hemolytic streptococci in the upper respiratory tract, the bronchial tree or duodenal contents of 10 adults suffering from urticaria. Elimination of the infection was followed in every case by subsidence or disappearance of urticaria. Prontylin, Prontosil and sulfanilamide therapy caused the disappearance of beta hemolytic streptococci from the stool and duodenal fluid, but had no effect on alpha hemolytic streptococci.

The use of histaminase in the treatment of urticaria seems to be based on sound physiologic knowledge. Therefore, it has been employed clinically with keen and hopeful anticipation. For many years histaminase has been used in Europe in the form of Torantil in the attempted treatment of all the manifestations of allergy. In reference to

the use of Torantil in this country, Goodman and Sulzberger³⁸ state:

Almost all the investigators now agree that the drug has proved generally disappointing, although its effect may have seemed beneficial in isolated instances. Allergists and dermatologists in this country will watch the results of the next few years work with histaminase with considerable interest. Our own experience with histaminase (Torantil) in all forms of allergy, as well as in urticaria due to cold or other factors, has thus far failed to demonstrate any therapeutic effect.

Markel³⁹ has reported a case of chronic urticaria and angioneurotic edema associated with signs of pancreatic insufficiency. The administration of deinsulinized pancreatic extract resulted in a cure. Although cases of this type must be uncommon, this case serves as an example showing the extremely bizarre etiologic interplay seen in urticaria, and it serves also as one further item which may be added to our therapeutic legerdemain.

The endocrinologic approach to the urticaria problem deserves thoughtful consideration, and further advances in the field of endocrinology may shed valuable light on the problem of therapy. It is well recognized that acute attacks of urticaria may be relieved at least temporarily and partially by injections of adrenalin. Cases of chronic urticaria have been known to respond successfully to thyroid medication, when many other measures had failed. It may be remembered that the drug, thyroid, sensitizes the neuromuscular function to the action of the patient's own circulating adrenalin. Perhaps urticaria is actually a type of imbalance between the two divisions of the autonomic nervous system—sympathetic and parasympathetic. Atropine, ephedrine, pilocarpine and other drugs and the hormones have powers of influencing the autonomic-nervous-system balance. Perhaps a drug or hormone more effective in its influence on the activity of the autonomic nervous system will be found and will be of great value in the symptomatic treatment of hives.

POISON-IVY DERMATITIS

In an entry dated October 9, 1748, Peter Kalm gave in his account of his travels in North America an extensive and interesting description of the *Rhus radicans* of Linnaeus. Since that time there have been many accounts of these plants and of their toxic nature. Even before 1748 there was a clear-cut account of severe suffering from poison-ivy dermatitis, which was contracted in New Mexico by the members of a Spanish expedition, under Governor Valverde, sent to that area in 1719 (McNair⁴⁰).

Of all the skin eruptions caused by plant substances, that produced by the different species of

Rhus is probably the commonest in North America. *R. toxicodendron*, *R. radicans* and *R. diversiloba* form a triad of plants regarded equally with caution and aversion. The recognition of their injurious character is shown in the application of the names, "poison ivy," "poison vine" and "poison oak," given to them in various parts of the United States. Shelmire,⁴¹ commenting on this three-leaved, white-fruited form of the *Rhus* family, makes statements of considerable interest. In addition to the various species of the *Rhus* family already mentioned, he lists *R. quercifolia*, *R. microcarpa* and *R. rydbergii*, and he reasons as follows:

Some botanists still contend that slight differences exist between these many forms, basing their contentions on whether the habit of growth of the plant is chiefly erect or climbing and on variances in the texture, pubescence and degree of lobing of the leaflets. Since all these variations can be observed in the same species under different climatic, soil and other field conditions, conservative taxonomists now agree that the numerous species of poison ivy are identical. I have patch tested ivy-sensitive persons with acetone-diluted oleoresins extracted from the many so-called species of ivy collected in different sections of the United States and have found the antigenic potencies of the various specimens to be identical.

Shelmire's experiments indicate that the dermatitis-producing principle of poison ivy is not an oil, as previously described, but a dialyzable fraction of the oleoresin soluble in water and urine.

Poison-ivy dermatitis is a skin disease that, as a rule, is diagnosed easily, but it cannot be diagnosed with absolute accuracy on the basis of the skin appearance alone. It is advisable always to elicit a careful history to eliminate the other venenatas and contact dermatoses, which present pictures identical with that seen in poison ivy. The dermatoses that may bear a close resemblance include those due to such allergens as the following: iodine, furs, dyes, cosmetics, tar, sulfur, chrysanthemum, primrose, sumac, sunflower, ragweed, celery, tobacco, tomato, orange, matches, phenol, cocobolo wood and formalin. This long list could be extended a great deal further with considerable ease, but it serves as it stands to indicate the numerous pitfalls that easily creep into the diagnosis of poison-ivy dermatitis.

The ease with which this dermatitis is misdiagnosed accounts in part for the widely divergent opinions concerning therapy, particularly injections. It seems likely that many cases treated by injections of the *Rhus* antigen are not really caused by poison ivy but by totally unrelated substances and hence are not likely to respond to ivy-antigen injections.

An acute dermatitis presenting clear-cut vesicles

with or without bullae and appearing suddenly on exposed regions of the body should always arouse suspicion of dermatitis venenata. In the summer months an acute vesicular dermatitis involving the face, hands and genitalia should always call for inquiry concerning ivy, primrose or other plants. In the colder season a similar eruption around the neck suggests investigation of the possibility of allergic reaction to collars and scarves containing fur, wool, silk or dyes. At any season a dermatitis in the scalp, spreading over the forehead, ears and neck, should lead to inquiry regarding hair dyes. These simple facts reviewed even briefly as one inspects and studies a clear case of dermatitis venenata should help to prevent a hasty and erroneous diagnosis of poison-ivy dermatitis.

The distribution of poison-ivy dermatitis need not be limited to hands, face and genitalia, but may involve any area of the body. As a rule, one makes no effort to account for the bizarre areas of distribution that are seen. However, the effort to inquire into and determine possible mechanisms to account for any particular type of distribution may be rewarded by interesting findings concerning this subject. One patient of mine had been exposed quite definitely to poison ivy, but had the disease only on the thighs and buttocks. He recalled no direct contact with the plant except with his gloves and other articles of clothing. On careful questioning it was discovered that after he came in from chopping wood he took off his trousers and laid them on a chair. He then sat down on the trousers as he unlaced and removed his shoes and stockings. The distribution was thus accounted for. In this case, the hands showed no evidence of the disease, although they must have come in contact with the poison ivy on his clothing. The hands escaped the disease in this case probably because they were washed with soap and water before the ivy allergen could initiate dermatitis. As a rule, people wash their hands far more frequently than other parts of the body. In studying the distribution of poison-ivy dermatoses, it should be helpful to remember that even in the most violently susceptible subjects all areas of skin may not be allergic to poison ivy, and that some areas may be quite resistant to it, as proved by patch tests.

Internal manifestations of poison-ivy poisoning may occur. The majority of such cases have been caused by chewing the leaves or by swallowing the juice to obtain immunity. One of these cases terminated fatally (Alumbaugh⁴²). The internal form of the disease sometimes occurs after eating the poison-ivy fruit, particularly if it is unripe. In such cases the patient usually becomes

drowsy and stuporous, later vomits a wine-colored fluid and finally may go into convulsions.

Prophylaxis and Treatment

Protection against poison-ivy dermatitis may be afforded by application of an oxidizing agent to the skin prior to deliberate exposure to the plant. Potassium permanganate solution (0.1 per cent) and ferric chloride solution (3 to 5 per cent) have been found to be useful. The potassium permanganate method, however, has the disadvantage of staining, and the ferric chloride method carries the risk of permanent iron deposits in the skin. Schwartz, Warren and Goldman⁴³ have found that complete protection of the skin against the action of the poison-ivy plant can be accomplished by application to the hands and forearms of a preparation containing 10 per cent sodium perborate incorporated in a base of vanishing cream. After such an application, a white deposit is left on the skin. Poison-ivy leaves may then be plucked and brushed against the skin without deleterious effects. Farmers, horticulturists, gardeners and men engaged in clearing land of poison ivy can obtain complete protection by the use of this cream. Application of the substance should be made in the morning and removed at noon with soap and water, which removes not only the sodium perborate but also the poison-ivy deposits. In the afternoon, when the patient returns to work, the cream should be reapplied.

The problem of the treatment of poison-ivy dermatitis is that of skillful selection and proper application of oxidizing, drying and antipruritic agents. In addition, there is the controversy about whether or not injection of poison-ivy extracts should be employed. Of course, in all cases one must adapt the treatment to the patient's idiosyncrasies. The past experiences of the patient are usually an excellent aid in working out a program of care particularly suited to the individual case.

It seems as though no type of topical application has any consistently dramatic effect in the treatment of poison-ivy dermatitis. In my experience, the dramatic results from therapy have seemed to come mostly from the use of poison-ivy extracts given by intramuscular injection. When such excellent results are obtained, they have come about only after the administration of at least four daily injections of the extract and only after the passage of about twenty-four hours after the fourth injection. I have used Lederle's poison-ivy extract, given in 1-cc. doses by a careful technic devised to ensure deep intramuscular injection and to avoid placing any of the material on the skin or in the subcutaneous spaces. Naturally, if the poison-ivy extract comes in contact with the skin, the usual

dermatitis is likely to result. If the extract is introduced into the subcutaneous spaces or if it leaks back into these spaces from the muscle, severe local reactions are apt to occur. Following intramuscular injection, immunity develops in various degrees. It is well recognized that having had poison-ivy dermatitis provides no immunity, and one attack is apt to be followed by years of recurrent attacks, unless injection therapy is used or unless the plant is avoided. There is no doubt that severe allergy to poison ivy may subside spontaneously, but it is more apt to take place by a very slow and gradual process, probably requiring complete avoidance of the plant for years.

Topical applications of value in the treatment of poison ivy include the following: potassium permanganate solution (0.02 per cent), boric acid solution (2 per cent), Burrough's solution (diluted 1:16) and carbolized zinc oxide lotions. Iron salts such as ferric chloride are no longer recommended because of the permanent iron deposits occasionally seen. In my opinion, the best and safest oxidizing agent is potassium permanganate.

It is of great importance to remember, when treating all types of dermatitis venenata, that the local therapy is exclusively a drying type of procedure and that after several days of such treatment the skin may become excessively dry. At this stage, itching may be due to dryness and not to vesiculation. After the disappearance of vesiculation it is desirable to use a grease, which will often give considerable relief from discomfort. It is contrary to the best accepted opinions to use any kind of grease before the disappearance of vesiculation. The allergen of poison ivy is soluble in oils and greases, and it is possible to disseminate the poison considerably by the premature use of ointments. The use of a grease in the late dry stages of poison-ivy dermatitis is an entirely different matter, as already indicated.

Opinions regarding the injection therapy and prophylaxis of poison-ivy dermatitis are widely divergent. Caulfield,⁴⁴ of Toronto, employed poison-ivy extracts in therapy and prophylaxis and obtained very favorable results. He found that intramuscular injection of this extract lessened the severity and duration of an attack, and he succeeded in showing that after these injections the patch tests with poison-ivy material became less strongly positive or even completely negative. He demonstrated evidence that clinical immunity to ordinary contact with poison ivy could be produced by these injections.

The present status of the therapy and prophylaxis of poison-ivy dermatitis by the injection method has been summarized recently by Good-

man and Sulzberger.³⁸ It is appropriate to quote an excerpt from their paper:

The following are among the authors who have reported favorable results from administration of extracts in the specific treatment of ivy dermatitis. Strickler, Williams and MacGregor, Bivings, Clock, Gowen, Sharlit and Caulfield.

The following are among those who have reported no beneficial effects of extracts used in specific treatment: Krause and Weidman, Corson and Sompeyrac.

Among others, the following have reported the specific extracts to be effective in prophylaxis of poison-ivy dermatitis: Clock, Gowan, Blank and Coca, Biederman, Caulfield, and Molitch and Poliakoff . . .

On the other hand, there are some authors who report that specific injections are of no prophylactic value. These include Bachman, and . . . Zisserman and Birch, with a controlled study on a group of 1731 boys

Wright⁴⁵ states that he has administered the tincture of *R. toxicodendron* by mouth and has obtained with it excellent results both during the attack and, particularly, in the prevention of ivy poisoning. He has described carefully his technic for using the tincture. Wright also recommends the injection therapy of poison ivy.

X-ray therapy is a useful aid in poison-ivy dermatitis and is often employed in severe and stubborn cases. It is effective in dosage so small as to involve no hazard whatsoever.

CASE 27151

PRESENTATION OF CASE

A twenty-nine-year-old married seamstress entered the hospital complaining of attacks of "coma."

The patient was well until three years before admission, when she noticed the onset of dizzy spells occurring about eleven o'clock in the morning during which she felt faint. Further, the patient felt weak and almost continuously hungry. Two and a half years before admission, at the same time one morning, she began to perspire freely, her mind became "paralyzed" and she went into "coma." This state lasted for seven hours, and although friends said that she walked and ate during the first two hours, she remembered nothing. The patient stopped work for five months, but then returned and shortly afterward had another attack of "coma." In the morning two days later, after having some teeth extracted, she could not be roused, so that the family physician advised immediate entry to a hospital, where the patient regained consciousness; a skull plate was negative, but a blood-sugar level of 35 mg. per 100 cc. was recorded. The patient was given "mixed gland pills" and a high-calorie, high-fat diet, with seven meals a day. Under this regime she felt better and gained weight and strength, but her appetite was not easily appeased and she lacked her former energy. The attacks of "coma," although milder, still occurred two or three times a month and seemed to have a relation to menstruation. In general the attacks appeared before mealtime when the patient felt weak and hungry and had worked too hard around the house. The spells were ushered in by marked perspiration, dizziness and lack of concentration, but they occasionally appeared without warning; sometimes she could hear, but was unable to respond or complete an intended action. Loss of consciousness could be prevented by drinking cocoa or coffee with sugar, and after such an attack she felt chilly. The patient had gained 40 pounds in the last two and a half years.

The family history was irrelevant. The patient had one child, born a few months before the onset of her present illness.

Physical examination was essentially negative. The blood pressure was 110 systolic, 70 diastolic.

The temperature, pulse and respirations were normal.

The urine was normal. Examination of the blood showed a red-cell count of 4,940,000 with a hemoglobin of 90 per cent, and a white-cell count of 10,500. The fasting blood sugar ranged between 38 and 41 mg. per 100 cc., the nonprotein nitrogen was 24 mg., the protein 6.4 gm. and the cholesterol 144 mg. per 100 cc., and the chlorides 103.1 milliequiv. and the carbon dioxide combining power 28.7 milliequiv. per liter. A blood Hinton reaction was negative; the stools were normal. A glucose-tolerance test using 100 gm. of glucose gave a fasting sugar of 26 mg. per 100 cc., 102 mg. in thirty minutes, 196 mg. in one hour, 220 mg. in two hours and 246 mg. in three hours. An insulin-glucose-tolerance test using 6 units of insulin subcutaneously and 100 gm. of glucose by mouth gave a fasting sugar of 30 mg. per 100 cc., 89 mg. in twenty minutes, 102 mg. in thirty minutes, 93 mg. in forty-five minutes, 74 mg. in one hour. At the two-hour mark, when the blood sugar was 90 mg. per 100 cc., 0.6 cc. of adrenalin was given subcutaneously. Forty-five minutes later the sugar was 93 mg., and one hour later 114 mg. A 17-ketosteroid assay was 9 mg. per 100 cc.; the basal metabolic rate was -6 per cent.

X-ray studies of the skull and chest and a gastrointestinal series were negative.

DIFFERENTIAL DIAGNOSIS

DR. REED HARWOOD: There can be no doubt that this woman was suffering from hypoglycemia. The symptoms are typical and were relieved by the ingestion of food. The most probable cause is hyperinsulinism, but we must first consider other possibilities in the differential diagnosis. Addison's disease can be accompanied by hypoglycemic attacks. We can exclude that diagnosis in this case by the physical examination and the normal 17-ketosteroid assay. In hypopituitarism, hypoglycemic attacks are frequent and troublesome, but again we have a physical examination that would exclude it, not to mention the normal menstrual periods and the normal 17-ketosteroid assay. Hypothyroidism in certain liver diseases can cause a tendency toward hypoglycemia, but rarely would a patient have such a low blood-sugar level as is present in this case.

Let us imagine that we are the physician in charge and that we must decide what to do with this patient. She was in an extremely precarious situation. Although the attacks had been fairly well controlled in the past, there was no telling

when she might be unable to absorb enough glucose because of gastroenteritis, seasickness or anything of the sort. There is no way of telling when she might overexert herself or for some reason be unable to get food quickly. She might suffer serious cerebral damage or die in an attack. It was therefore necessary to explore the pancreas in the hope of finding a tumor of the islands of Langerhans. Since we know that some of these tumors become malignant, we have a second reason for exploration.

Will the surgeon find a tumor? In a good proportion of the reported cases the surgeon has been unable to find one. In some cases a single small nodule or several small nodules are found. Occasionally a single large tumor of the pancreas is found and sometimes extensive metastatic cancer with metastases in the liver. I do not believe that cancer was present in this case, since the symptoms did not progress during the three years. If the surgeon is unable to find a tumor he may elect to resect a good portion of the pancreas in the hope of alleviating the attacks. If this were done, Dr. Mallory may tell us that the pancreatic islet tissue shows hyperplasia, but cases have been reported in which no abnormality was noted in the pancreas. Some patients have been operated on repeatedly; sometimes at a second or third operation a tumor is found, and sometimes one is never found. It is impossible to predict, with the findings that we have, what would be found at operation. Since the gastrointestinal x-ray films were normal, I am going to guess that the tumor was not a large one.

I might say a word about the glucose-tolerance and glucose-insulin-tolerance tests, which have not been found helpful in establishing a diagnosis in these cases. In hyperinsulinism, any type of curve may be found. In this particular case the glucose-tolerance test showed that the patient's own pancreatic tissue was unable to handle a large test dose of glucose. This can mean that the patient had diabetes mellitus as well as hyperinsulinism,—such cases have been reported,—or it can be explained on another basis. In the presence of an islet tumor, the normal islet tissue may not be functioning properly. The glucose-insulin-tolerance test simply showed that the patient was not insulin resistant. The most significant test in hyperinsulinism is the fasting blood sugar.

CLINICAL DIAGNOSIS

Islet tumor of pancreas.

DR. HARWOOD'S DIAGNOSES

Hyperinsulinism.

Adenoma of the islands of Langerhans ?

ANATOMICAL DIAGNOSIS

Adenoma of pancreatic islet cells.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This patient was explored by Dr. Leland S. McKittrick and Dr. Edward D. Churchill, with a diagnosis of probable islet tumor of the pancreas. After a very long tedious exploration, almost given up at one point, a small area of the pancreas was finally found that seemed to be of slightly different color and consistence from the rest. It was outlined so vaguely that they were uncertain where the borderline was between the tumor and the surrounding pancreatic tissue. Therefore, a margin of presumably normal pancreas was resected with the suspected tumor. The specimen was immediately divided in half, part of it delivered to the chemists for insulin assay, and the other half run through for sections. Unfortunately, it was still impossible to be certain what was tumor, and the specimen that was sent for assay turned out to be normal pancreas, showing a normal insulin content. The material we saved for histologic examination we again divided in two parts, one of which we put in ordinary fixative, the other in a special fixative, thinking we would try to stain the beta granules. The part we put in special fixative turned out to be normal pancreas, showing beautiful granules in the islets. The part we put in the ordinary fixative did prove to be an adenoma, but all our efforts at special investigation were fruitless. Further proof that this was an islet tumor of the pancreas is furnished by the postoperative course of the patient.

DR. EUGENE SULLIVAN: She has been followed carefully since her operation in October, and was last seen one month ago. We were somewhat disturbed immediately postoperatively that one or two blood-sugar determinations were rather low. However one of these specimens had apparently clotted by the time it got to the laboratory. The recent specimens show a fasting blood-sugar range of 70 to 80 mg. per 100 cc. in comparison with the ones taken beforehand, which were in the neighborhood of 40 mg. She has not had a single hypoglycemic attack since operation.

CASE 27152

PRESENTATION OF CASE

A forty-three-year-old woman entered the hospital complaining of shooting pains in the right leg. The patient stated that approximately three years before admission she tripped on the stairs

and fell on her right knee and shin, scraping the skin rather badly. Since that time she had been unable to kneel on that knee and had had intermittent, mild pain in the upper right leg aggravated by walking. One month before admission the pain in the upper shin became much worse and often kept her awake. During the year before entry, the patient had gained 20 pounds and had suffered from frequent frontal headaches, and for six months, vision had failed gradually in her left eye.

The patient had had diphtheria and tonsillitis. She was the mother of ten children, and had had one abortion, and two premature births occurring at seven months, neither of the infants surviving.

On examination the patient was well developed and well nourished and in no apparent distress. The scleras were clear; the pupils were equal and regular, and reacted to light and accommodation. A rosebud-shaped posterior polar cataract was present in the left eye. Examination of the heart, lungs and abdomen was negative; the blood pressure was 110 systolic, 70 diastolic. Rectal examination showed hemorrhoids and a slight rectocele. There was a fusiform, tender swelling of the upper third of the right tibia along its anterior border. The skin over this swelling showed a brownish pigmentation; the temperature was not increased. Arterial pulsations were present in both legs. Examination of the nervous system was negative.

The temperature, pulse and respirations were normal.

Examination of the urine showed a + test for albumin; Bence-Jones protein could not be demonstrated. Examination of the blood showed a red-cell count of 4,350,000 with a hemoglobin of 75 per cent, and a white-cell count of 5700 with 65 per cent polymorphonuclears. The sedimentation rate was 28 mm. in one hour. The nonprotein nitrogen of the blood serum was 20 mg., the calcium 10.6 mg., the phosphorus 3.5 mg. and the phosphatase 2.6 Bodansky units per 100 cc. Blood Hinton and Wassermann reactions were positive; agglutination reactions against typhoid and paratyphoid bacilli and *Brucella abortus* were negative. A lumbar puncture gave an initial pressure of 150 mm. of spinal fluid. On examination of the fluid there was no increase in cells; the protein was 75 mg. per 100 cc., the gold-sol curve 2223331000, and the Wassermann reaction positive.

X-ray films of the right leg taken in the Out Patient Department one month before admission showed extensive, irregular periosteal new-bone formation along the anterior and lateral aspects of the right tibia. The changes were particularly marked below the tibial tuberosity. An area of localized bone destruction was also present in this region, and there was some soft-tissue swelling.

An x-ray film of this region at the time of admission showed a definite increase in the periosteal proliferation over the upper end of the tibia. The entire upper third was involved up to the margin of the joint cartilage. There was apparent fluid in the knee joint, and edema of the soft tissues overlying the periostitis. There were still no large areas of bone destruction and no sequestra. The left tibia appeared normal. X-ray studies of the skull, ribs and bones of the pelvis were not abnormal. A chest plate was negative, with no evidence of metastases.

On the fourth hospital day a biopsy was performed.

DIFFERENTIAL DIAGNOSIS

DR. CLIFFORD C. FRANSEEN: May we see the x-ray films?

DR. GEORGE W. HOLMES: The location of the lesion is where we should expect to find syphilitic periostitis. The whole cortex is thickened. The endosteum is somewhat thickened, as well as the periosteum, so that the medullary canal is narrow. That again is in favor of a syphilitic lesion. If we look carefully at the lesion itself, the new-bone proliferation has the looped appearance, sometimes called a "lacework appearance," that we associate with syphilis. If we confine ourselves to these earlier films, the lesion is rather characteristic of syphilis, but in the next set of films, taken a month later, a remarkable change has taken place for a syphilitic process that is not under treatment. Then in this film there are some lines that might represent true spicules. Any chronic inflammatory condition could produce that effect, but syphilis does it more often. I think it is very unusual to see it in tumors. A tumor of that extent should be accompanied by a large soft-tissue mass, particularly since it involves the surface of the bone.

DR. FRANSEEN: To go back to the duration, which is of great interest in this case, three years certainly suggests a low-grade, long-standing inflammatory process. The duration is also consistent with a benign lesion in which some change had taken place a month or so before admission, because the pain had become worse during the past month. The failing vision is later explained by the presence of a cataract. I do not know why a patient of this age had a cataract. I do not believe that we have to consider a metastatic melanoma from a primary tumor of the eye in this case, as the history of unilateral failing vision might have suggested. In the approximately 20 cases of this condition that I have seen at the Huntington and Palmer hospitals, I do not remember any in which there was metastasis to bone, but it does occur when the primary tumor is in other sites.

The next points of interest are the two premature births and the positive laboratory findings that have to do with syphilis. The brownish pigmentation could be explained on the basis of longstanding chronic inflammation and need not be related to the brownish pigmentation of von Recklinghausen's disease, which might be suggested because of accompanying bone lesions. The sedimentation rate is barely elevated. The other blood findings are normal. The phosphatase is low, which is against osteogenic sarcoma with this much proliferative new bone present. With the phosphatase normal, the indication is that this new bone has been laid down over a long period of time. The normal phosphatase is also against Paget's disease. When new-bone formation occurs to this extent in metastatic carcinoma, the phosphatase might well be slightly elevated and would almost certainly be elevated to some extent with additional metastasis elsewhere. Both the Hinton and Wassermann reactions were positive, and this again focuses our attention on syphilis. It is difficult to explain why tests for agglutinins against typhoid and paratyphoid bacilli and *Brucella abortus* were performed. The patient had a low white-cell count, it is true. Periostitis does occur in typhoid fever, and I have been told that it also occurs in paratyphoid A fever, so that these tests may not have been so far afield as one would at first imagine. I remember reading of a case of periostitis of the rib in a patient who had typhoid eighteen years previously; a pure culture of typhoid bacilli was obtained from an abscess beneath the periosteum. I do not know that periostitis ever occurs in brucellosis. The lumbar puncture showed findings consistent with tabes: elevated protein, suggestive gold-sol curve and positive Wassermann reaction. The patient had no Argyll-Robertson pupils, however. So much for what we learn by the history and physical findings.

We must also consider other infectious conditions. I think that tuberculosis can probably be ruled out because of the age of the patient and other factors. A low-grade osteomyelitis might be considered. The descriptions of the sclerosing forms of osteomyelitis simulate this picture to some extent, but I have not known of a case of as long duration as this, so that perhaps we need not enlist that diagnosis. Syphilis certainly must be kept in mind, since this lesion, which Dr. Holmes has described, is entirely consistent with syphilitic periostitis. Dr. Holmes and Dr. James R. Lingley described the bone lesions in syphilis three years ago; they suggested that syphilis can simulate practically any bone lesion one can name, and also that it not infrequently follows trauma.

This is also the site in which syphilis of the bone commonly occurs.

So far as neoplasms go, osteogenic sarcoma might be possible from the x-ray examination, but we cannot reconcile it with the duration, the absence of soft-tissue tumor swelling and other factors. The same thing is true of fibrosarcoma contiguous to bone, with periosteal reaction. Ewing's tumor similarly tends to form more of a tumor. It is difficult to make a diagnosis of a malignant bone lesion with a duration of three years, if we can believe that the patient had some process there during the entire period. There is nothing to support myeloma or lymphoma of bone or reticulum-cell sarcoma. She was in the age group in which metastatic cancer might be considered, without lesions elsewhere, but this would be an extraordinary picture for metastatic carcinoma. I remember, however, a patient who had a single metastatic lesion in the tibia, — more destructive than this, it is true, — which was the only lesion in her body of a recurrence of a carcinoma of the breast.

We must keep in mind metabolic diseases, but we have no evidence of anything in the laboratory findings to support such a diagnosis.

We are led so completely to the diagnosis of syphilis of bone that I fear there may be some trap, yet I do not believe we can justifiably make any other diagnosis in view of the x-ray findings, the history and the positive laboratory findings. Despite the diagnosis, I believe a biopsy is indicated for confirmation because of the rapid change in the appearance of the lesion by x-ray examination during the last month. My diagnosis is syphilis of bone.

CLINICAL DIAGNOSIS

Syphilis of bone.

DR. FRANSEEN'S DIAGNOSIS

Syphilis of bone.

ANATOMICAL DIAGNOSIS

Syphilitic periostitis.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: A biopsy of the tibial cortex was performed, and the microscopic examination showed new-bone formation, with marked fibrosis and inflammatory reaction. In the inflammatory tissue, leukocytes and plasma cells predominated, but there were also focal clusters of epithelioid cells that were fairly characteristic of miliary gummas, so that the diagnosis of syphilis is substantiated.

SUBSCRIPTION TERMS. \$6.00 per year in advance, postage paid, for the United States, Canada, \$7.04 per year, Boston funds, \$8.52 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Saturday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston, Massachusetts.

AMERICAN COLLEGE OF PHYSICIANS

DURING the week commencing April 21, the twenty-fifth annual session of the American College of Physicians will be held in Boston, with general headquarters at the Hotel Statler.

In general the program is as follows: hospital clinics and lectures in the mornings, followed by panel discussions; general sessions in the afternoons; and a variety of entertainment in the evenings, including a Symphony Concert on Tuesday, April 22, and the annual banquet on Thursday, April 24. Detailed information can be obtained from Dr. William B. Breed, 264 Beacon Street, Boston, chairman of the Committee on Arrangements.

Registration is not limited to members of the

American College of Physicians. The following will be admitted without registration fee to practically all the sessions on the presentation of proper credentials at the registration desk: all members of the medical corps of the United States Army, Navy and Public Health Service; members of the staff, including interns, of the hospitals participating in the program; and all fourth-year students of approved medical schools. Furthermore, duly qualified physicians are permitted to register as visitors; this entails a fee of \$12.00, and entitles the registrant to one year's subscription to the *Annals of Internal Medicine*, the official organ of the college.

The Massachusetts Medical Society and the *Journal* extend a hearty welcome to the members of the American College of Physicians, and trust that the success of the meeting will be such that an early return to New England will be guaranteed.

WHY THE MARRIAGE PROTECTION BILL?

House Bill 469 has passed the Committee on Public Health of the Legislature and soon will be reported for action to the House of Representatives. This bill provides that a couple before applying for a marriage license shall consult a physician, who shall make physical examinations and shall take specimens of blood for serologic tests. He must then sign a certificate that he has completed these examinations, and must further communicate his findings to both parties. Thereafter he may treat or deal with the situation privately, according to his best judgment. There is no publicity.

This is a constructive measure that puts squarely on the shoulders of the family physician the responsibility for premarital examination and advice. The traditional patient-physician relation is not violated.

Since the recognition of insanity, tuberculosis, hereditary and many other diseases is as important as that of the widely advertised genito-infectious diseases, the incidence of which seems

to have been much overstated, the thorough examination suggested by this bill is commendable medical practice and should in no case be slighted. The passage of the bill is therefore recommended.

OBITUARY

JOHN PRESTON SUTHERLAND

1854-1941

In the night of February 22, John Preston Sutherland passed peacefully and quickly from this sphere of human endeavor into the fuller life of the Great Beyond. Born in Charlestown, Massachusetts, on February 9, 1854, he inherited from his Scottish ancestry those qualities of mental acumen and physical vigor that made it possible for him to endure the stresses of a crowded and accomplishing life well beyond the scriptural three-score years and ten. Although advancing age had necessitated some curtailment of his activities, he remained young in spirit, and had been able to attend patients in his office the day preceding his death.

The brief space available for this sketch makes it possible to consider in a cursory manner only a few of the outstanding characteristics of this truly remarkable man. And primarily we think of him as the physician. Dr. Sutherland graduated from Boston University School of Medicine in 1879 and immediately opened an office in Concord. In 1881 he moved into Boston, and had constantly practiced there since that time. He rapidly developed a large clientele, numbering among his patients many people of prominence. His conscientiousness and painstaking thoroughness soon resulted in his recognition as a physician of exceptional skill; and his kindly and sympathetic manner endeared him to his patients, and gained lasting friendships and loyalties. His colleagues in the profession acknowledged him to be a keen diagnostician and successful prescriber, and he came to be in wide demand as a consultant, making journeys to all parts of New England. He was a firm believer in the homeopathic principle of drug therapy. He served many years as a visiting physician in the Massachusetts Homeopathic Hospital and was a trustee of the hospital. He also served as a consulting physician on the staffs of several other institutions.

As a teacher and educator Dr. Sutherland was peculiarly gifted. His analytical mind and attention to details, his orderly and logical presentation of his subject matter, and his enthusiastic and convincing manner stimulated in his students an ambition to become proficient in the subjects that

he taught. His first appointment in Boston University School of Medicine was in 1881, as an assistant in clinical medicine; but his advance was rapid until, in 1888, he was elected professor of anatomy, a position that he held until 1907. He served as professor of theory and practice from that date until 1937, when he became professor of medicine, a position that he held at the time of his death.

Another of Dr. Sutherland's prominent characteristics was his executive and administrative ability, which was early recognized by his associates in the faculty of the medical school and resulted in his appointment as registrar in 1896, and acting dean in 1898. He was elected dean in 1900 and held this office until 1923, when he became dean emeritus. His conduct of the affairs of the school was distinguished by impartiality, skillful handling of men and conditions, and courageous and optimistic dealing with difficult situations. His ability to carry out his policies without arousing lasting antagonisms brought the school through many trying periods. These qualities were generally recognized and appreciated. He served as president of several local, state, national and international organizations, and occupied many positions of trust and responsibility in various fields of endeavor.

Dr. Sutherland was a prolific writer and produced innumerable papers on medical and scientific subjects, which were presented at professional gatherings both in this country and abroad. Many of them appeared in regular publications or in the form of brochures. For fourteen years he was the editor of the *New England Medical Gazette*, and during several years was on the editorial staff of the *New England Journal of Medicine*. In 1937 he completed a book that was published under the title, *Malnutrition: The medical octopus*, detailing his observations and conclusions based on the result of many years of study and experimentation with foods in their relation to health and disease.

Dr. Sutherland was a warm-hearted, self-sacrificing, cultured "gentleman of the old school," one of "God's noblemen." No student ever appealed to him for advice or assistance in vain; no colleague ever failed to receive co-operation and help in response to a request; no worthy cause was ever presented to which he did not give careful consideration and appropriate response. His high ideals and noble purposes have profoundly influenced the lives and actions of many of his students and associates. He disliked artificiality and grossness in persons or material things, and was an ardent lover of nature in all its manifestations. Extensively traveled, widely read and intensely interested in and conversant with a variety

of subjects, he was truly "a man of sovereign parts"

Many honors came to Dr Sutherland in the forms of elevation to high office, appointment to positions of trust, resolutions, memorials and gifts, but there are two which deserve especial mention. In 1923 the Trustees of Boston University conferred on him the honorary degree of Doctor of Science, and in 1937 the alumni of Boston University School of Medicine presented to the school a bronze bas relief, which was placed upon the entrance wall as a permanent memorial of the completion of over fifty years of service by Dr Sutherland to his alma mater. The plaque displays a fine portrait of him, with a suitable inscription concluding in the following words "Presented by his students as a tribute to an alert observer, a skillful teacher and an understanding friend"

Dr Sutherland held strong religious convictions, with an unflinching belief in the influence of a Supreme Being on human activities, and the expanding opportunities for service in a future life. The following poem by Walter Clarke Rodman, entitled, "Adventure," of which Dr Sutherland was very fond and which was read at the largely attended and impressive funeral services, seems fittingly to express his creed

To live, to love, to die, to live again,
This is the all of being, but how large
Looms that adventure in the afterward!

Nor life, nor love may here survive, but there
Shall both endure, nor by endurance lose
Their zest. New opportunities for use,
New scenes, new joys, a sense of gratitude
For things mysterious made manifest
Shall there be mine, and not a thought intrude
Regretful of the past. My soul awaits
Expectant the transition Do I hear
The plash of Charon's oars?

Ho! Ferryman

Thus say!

MEDICAL EPONYM

HEGAR'S SIGN

"Ein neues sicherendiagnostisches Zeichen der Schwangerschaft in den ersten Monaten [A New Infalible Diagnostic Sign of Pregnancy in the Early Months]" was described by C Reinl, of Franzensbad, in the *Prager medicinische Wochen schrift* (9 253, 1884) as a contribution from the clinic of Alfred Hegar (1830-1904) at Freiburg. A portion of the translation follows

During the course of the past winter the opportunity was afforded me, at the gynecologic clinic of Herr

Geheimrat Hegar, of acquainting myself with an excellent new sign of pregnancy in the first months

This consists in the demonstration of an unusual softness, pliability and thinning of the lower uterine segment, that is, the portion immediately above the insertion of the sacrouterine ligaments

This condition of the parts mentioned is not only demonstrable if the remainder of the fundus, as is not at all uncommon, feels firm and hard, but also when it is soft and elastic

The pliability and flabbiness of these parts may be so marked as to cause one to doubt whether there is any connection between the cervix and the larger swelling in the abdomen or pelvis

HEART DISEASE IN PREGNANCY WITH FATAL OUTCOME

A thirty six year-old primipara was seen early in pregnancy by her doctor

The past history included rheumatic fever ten years previously, with ensuing rheumatic heart disease. Five years later, the patient suffered from cardiac decompensation

At the time of the first visit, examination showed that she had mitral stenosis and aortic stenosis and insufficiency. The patient was told very plainly the probable outcome of her case if she continued with the pregnancy, but she insisted that it should not be interrupted

The pregnancy progressed fairly well, with the aid of digitalis and rest, until the patient was between five and six months pregnant. At this time the heart became decompensated, and a cardiologist was called in consultation. He referred her immediately to the hospital. She was placed in an oxygen tent and was given cardiac stimulants, including digitalis. She seemed to respond slightly, but suddenly developed marked pulmonary edema and died undelivered fifteen days after admission. It was thought that the terminal event might have been due to a pulmonary embolus. Permission for an autopsy was refused

Comment This is another case procured from the Maternal Mortality Study, a fact which explains the absence of the specific details concern

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section

ing the heart that would naturally have been available in a private case. It illustrates how serious Grade A heart disease may be when complicated with pregnancy. This patient should never have been allowed to become pregnant. In the presence of pregnancy, provided one were thinking only of the medical side, therapeutic abortion should have been performed; this advice was given, but the patient refused to accept it.

The case was not too well handled from the start, since no cardiologist saw the patient until shortly before death. All such cardiac patients when pregnant should be under the care of a skilled cardiologist. This patient should have been in bed constantly. The case proves that organic heart disease is an extremely serious complication in pregnancy.

COMMITTEE ON STATE AND NATIONAL LEGISLATION

The following committee action has been taken on bills in which the Massachusetts Medical Society is interested:

FAVORED BILLS

H. 122. Bill (accompanying House 120, recommendations of the Department of Public Health) relative to requiring the clerk or registrar of each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. Referred to next General Court.

H. 130. Bill (accompanying House 120, recommendations of the Department of Public Health) relative to the sale of barbituric acid, its derivatives and certain other sedatives. Referred to next General Court.

H. 460. Petition of Leslie B. Cutler for legislation to regulate further the filing of notices of intention of marriage, the delivery of certificates of such intention and the return of unused certificates. Reported favorably.

OPPOSED BILLS

S. 502. Petition of Joseph C. Basso for legislation to provide for the regulation of the practice of osteopathy and for the establishment of a state board of osteopathic examination and registration. Withdrawn by petitioner.

S. 560. Petition of Bertram A. Harris and others for legislation relative to the qualifications of applicants for registration as qualified physicians and examinations thereof. Given leave to withdraw.

S. 623. Same as H. 609. Rejected in Senate.

H. 114. Bill (accompanying House 113, recommendations of the Board of Registration in Medicine) relative to providing for the annual registration of physicians and the biennial publication of the list of physicians duly registered. Reported favorably to Committee on Ways and Means.

H. 115. Bill (accompanying House 113, recommendations of the Board of Registration in Medicine) relative to the recording of the certificate of registration of a qualified physician by the town clerk. Reported favorably to Committee on Ways and Means.

H. 116. Bill (accompanying House 113, recommendations of the Board of Registration in Medicine) relative

to establishing a special commission to investigate and study the advisability and practicability of requiring special qualifications of all physicians who engage in the practice of surgery. Withdrawn by petitioner.

H. 272. Petition of Harold W. Sullivan that there be appropriated from the treasury of the Commonwealth the sum of twenty-five thousand dollars to provide for an investigation by the Board of Registration in Medicine relative to the practice of medicine. Given leave to withdraw.

H. 609. Petition of Annic D. Brown for legislation to provide further for regulating the practice of physicians and surgeons. Senate substituted S. 623.

H. 610. Petition of Annie D. Brown for amendment of the law regulating the practice of physicians and surgeons in certain cases. Given leave to withdraw.

H. 1618. Petition of D. N. Potter and others that certificates of vaccination or nonvaccination shall no longer be required as a prerequisite to attendance in the public schools or other institutions of the Commonwealth. Given leave to withdraw.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 13:

BERKSHIRE

Thursday, April 17, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. Management of Abdominal Distention. Instructor: Hollis L. Albright. Harry G. Mellen, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday, April 15, at 4:30 p.m., at the Union Hospital, Fall River. Chemotherapy in the Treatment of Gonococcal Infection. Instructor: P. N. Papas. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday, April 17, at 8:00 p.m., in the Library of the Franklin County Public Hospital, Greenfield. Dermatitis and Eczema. Instructor: Leonard E. Anderson. Halbert G. Stetson, *Chairman*.

HAMPDEN

Wednesday, April 16, at 4:00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Technic and Treatment of Primary, Secondary and Tertiary Syphilis. Instructor: Rudolph Jacoby. Alfonso A. Palermo, *Chairman*.

HAMPSHIRE

Thursday, April 17, at 4:15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Nutritional Deficiencies and the Uses of Preparations of Vitamins. Instructor: Maurice B. Strauss. Robert C. Byrne, *Chairman*.

WORCESTER

Tuesday, April 15, at 8:30 p.m., in the Nurses' Home of the Milford Hospital, Milford. Recent Advances in Medical Therapeutics. Instructor: Charles L. Short. Joseph Ashkins, *Chairman*.

WORCESTER NORTH

Friday, April 18, at 4 30 p m, in the Nurses' Home
of the Burbank Hospital, Fitchburg Pediatric
Case Discussions Instructor Lewis W Hill
George P Keaveny, *Chairman*

DEATHS

GODFREY—THOMAS F. GODFREY, M.D., of Springfield, died April 2. He was in his seventieth year.

Born in Northampton, he attended the University of Vermont and received his degree from the College of Physicians and Surgeons of Baltimore, Maryland, 1898. He was a former member of the Massachusetts Medical Society.

His sister and two brothers survive him.

GREENE—DANIEL C. GREENE, M.D., of Newton, died April 4. He was in his sixty-ninth year.

Born in Kobe, Japan, he attended Harvard University and received his medical degree from the Harvard Medical School in 1899. Dr. Greene had formerly been on the staffs of the Massachusetts General and Children's hospitals and was also on the teaching staff at Harvard Medical School from 1911 to 1930, first as a fellow and then as instructor in laryngology.

Dr. Greene was a fellow of the Massachusetts Medical Society and the American Medical Association, and had memberships in the American Laryngological, Rhinological and Otological Society and the American College of Surgeons.

His widow, two daughters and three sons survive him.

OTT—GEORGE J. OTT, M.D., of Boston, died March 1. He was in his seventy-fourth year.

Born in Bavaria, he lived in Clinton, Massachusetts until his graduation from medical school. He received his degree from the Albany Medical College in 1894, and was a fellow of the Massachusetts Medical Society and the American Medical Association.

WILLIAMS—HUBERT J. WILLIAMS, M.D., of Boston, died March 29. He was in his sixty-second year.

Born in Boston, he received his degree from Tufts College Medical School in 1901. He was a former member of the Massachusetts Medical Society and retired from active practice in 1932 because of ill health.

Two daughters survive him.

NOTICES

MEDICAL AND SURGICAL SUPPLY COMMITTEE

It will help England greatly in the care of victims of bombing raids and help England prepare for the coming invasion, if physicians in this country will give discarded or superfluous surgical instruments or surgical dressings.

Any such material should be sent to the Medical and Surgical Supply Committee, 420 Lexington Avenue, New York City.

WILLIAM HARVEY SOCIETY

The seventh lecture of the present series given under the auspices of the William Harvey Society of the Tufts College Medical School will be held in the auditorium of the Beth Israel Hospital on Friday, April 18, at 8

pri Dr George B Wislocki will speak on 'The Vascular Supply and Topography of the Mammary Pituitary Gland' Dr Benjamin Spector will preside

All interested members of the medical profession are invited to attend

BOSTON DOCTORS SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will give its second annual concert on Sunday, May 11, at 8 15 p m in Jordan Hall Alexander Thuede will conduct Dr Werner Mueller will appear as soloist

Proceeds of the concert will be used for the establishment of a fund for a free bed in each of the following hospitals: Beth Israel Hospital, Children's Hospital, Massachusetts Eye and Ear Infirmary and Boston Dispensary. Tickets at \$1.00 may be obtained by applying to Dr Julius Lomax, Pelham Hall Hotel, Brookline (BEA 2430)

NEW ENGLAND PEDIATRIC SOCIETY

A meeting of the New England Pediatric Society will be held on Wednesday, April 30. The clinical presentation will be held at the Children's Hospital, and all the other events at Longwood Towers, Brookline

PROGRAM

- 4 00 Clinical presentation by Dr Kenneth D Blickstein and his associates at the Children's Hospital
- 6 30 Refreshments
- 7 00 Dinner
- 8 00 Some Physiologic Peculiarities of the Premature Infant Dr Samuel Z Levine, professor of pediatrics, Cornell University Medical College New York City

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the staff of the Carney Hospital will be held in the auditorium of the Carney Hospital on Wednesday, April 16 at 11 30 a m

PROGRAM

- Case Reports
 - Orthopedic Dr A Leo Brett
 - Gynecologic Dr L E Phaneuf
 - Surgical Dr A M Fraser
- Clinicopathological Conference
- Physicians and medical students are invited to attend

ROBERT BRECK BRIGHAM HOSPITAL

Dr Albert B Ferguson will speak on Roentgenographic Features in Rheumatoid Arthritis at the Robert Breck Brigham Hospital on Tuesday, April 15, at 7 45 p m Drs Sidney Morrison and Aubrey O Hampton will lead the discussion

MASSACHUSETTS MEMORIAL HOSPITALS

There will be a staff meeting of the Massachusetts Memorial Hospitals at the Evans Memorial Auditorium on

Friday, April 25, at 8 15 p m Dr Samuel N Vose will be chairman

PROGRAM

- The Surgical Treatment of Deafness Dr Leighton F Johnson Discussion by Dr Philip E Meltzer
- Some Experiences with Ureteroenterostomy (illustrated by motion pictures) Dr George Gilbert Smith

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The New England Society of Physical Medicine will hold its monthly meeting at the Hotel Kenmore, Boston, on Wednesday, April 16, at 8 00 p m. The evening will be devoted to important business of the society. There will be no scientific program.

The council will meet at 6 00 p m, followed by an informal dinner at 6 30 p m

NEW ENGLAND PATHOLOGICAL SOCIETY

There will be a meeting of the New England Pathological Society on Thursday, April 17, at 8 p m at the Peter Bent Brigham Hospital

PROGRAM

- Tumors of the Peripheral Nerves Dr Arthur Purdy Stout, associate professor of surgery, Columbia University College of Physicians and Surgeons, and attending surgical pathologist, Presbyterian Hospital and Sloane Hospital for Women

MASSACHUSETTS SOCIETY FOR RESEARCH IN PSYCHIATRY

The next meeting of the Massachusetts Society for Research in Psychiatry will be held at the Monson State Hospital, Palmer, Massachusetts, on Tuesday, April 15. Luncheon will be served at 1 p m, followed by the program

PROGRAM

- Gingival Changes Produced by Dilantin Sodium Dr Leon J Robinson, Monson State Hospital
- Research in Mental Deficiency with Special Reference to Birth Injury Dr Clemens Benda, Wrentham State School
- Double Symmetrical Porencephalies Dr Paul Yarkovitz, Walter E Ferriell State School, and Dr Richard C Wadsworth, Metropolitan State Hospital

MEDICAL LIBRARY ASSOCIATION

The forty third annual meeting of the Medical Library Association will be held at the University of Michigan Medical School, Ann Arbor, Michigan, on Thursday, Friday and Saturday, May 29, 30 and 31, under the presidency of Col Harold W Jones, of the Army Medical Library, Washington, D C. Hotel headquarters will be at the Michigan Union. The program will include papers on the co-operation of libraries, union catalogues, medical history and industrial medicine

CALIFORNIA STATE PERSONNEL BOARD

The California State Personnel Board has waived the one year California residence requirement for applicants to fill current vacancies on the medical staffs of various

state institutions. All interested in positions as senior interns and student interns, which carry salaries as well as providing maintenance, should apply to Louis J. Kroeger, State Personnel Board, 1025 P Street, Sacramento.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 13

MONDAY, APRIL 14

12:15-1:15 p.m. Clinicopathological conference. Peter Bent Brigham Hospital amphitheater.

*7:30 p.m. Roentgenology of the Bones and Joints. Dr. Albert B. Ferguson. Evans Auditorium, 78 East Concord Street, Boston.

TUESDAY, APRIL 15

*9-10 a.m. Medical Ophthalmology. Dr. S. T. Clarke. Joseph H. Pratt Diagnostic Hospital.

*12 m. The Present-Day Treatment of Prostatism. Dr. Richard Chute. South End Medical Club. Headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston.

12:15-1:15 p.m. Clinicoroentgenologic conference. Peter Bent Brigham Hospital amphitheater.

*12:30 p.m. Medical Council of Boston. Palmer Memorial Hospital, 195 Pilgrim Road, Boston.

7:45 p.m. Roentgenographic Features in Rheumatoid Arthritis. Dr. Albert B. Ferguson. Robert Breck Brigham Hospital.

WEDNESDAY, APRIL 16

*9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*11:30 a.m. Monthly clinical meeting and luncheon of the staff. Auditorium, Carney Hospital.

*12 m. Clinicopathological conference. Children's Hospital.

8 p.m. New England Society of Physical Medicine. Hotel Kenmore, Boston.

THURSDAY, APRIL 17

*8:30 a.m. Combined clinic of the medical, surgical, orthopedic and pediatric services of the Children's Hospital and the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital.

*9-10 a.m. Endocrinologic Relation between the Hypophysis and the Eye: Problems and facts. Dr. J. Igersheimer. Joseph H. Pratt Diagnostic Hospital.

8 p.m. Tumors of the Peripheral Nerves. Dr. Arthur Purdy Stout. New England Pathological Society. Peter Bent Brigham Hospital.

*8:15 p.m. Problems in Urinary Lithiasis. Dr. Richard Chute. United States Naval Hospital, Chelsea.

FRIDAY, APRIL 18

*9-10 a.m. What Happens to Alcoholics. Dr. Merrill Moore. Joseph H. Pratt Diagnostic Hospital.

*8 p.m. The Vascular Supply and Topography of the Mammalian Pituitary Gland. Dr. George B. Wislocki. William Harvey Society. Beth Israel Hospital, Boston.

*Open to the medical profession.

BOOK REVIEWS

The Abnormal in Obstetrics. By Sir Comyns Berkeley, M.A., M.C., M.D. (Cantab.), F.R.C.P. (Lond.), F.R.C.S. (Eng.), M.M.S.A. (Hon.), F.C.O.G.; Victor Bonney, M.S., M.D., B.Sc. (Lond.), F.R.C.S. (Eng.), F.R.A.C.S. (Hon.), M.R.C.P. (Lond.); and Douglas MacLeod, M.S., M.B. (Lond.), F.R.C.S. (Eng.), F.R.C.P. (Lond.), M.C.O.G. 8°, cloth, 525 pp., with 6 illustrations. Baltimore: William Wood and Company, 1938. \$6.00.

This is a miniature encyclopedia of deviations from the normal in female reproduction. Although it is not a textbook, it may offer suggestions for explorations into the literature to one concerned with a specific abnormality or some effective factor in an obstetric or gynecologic condition.

Unlike most foreign textbooks, this one shows a fair knowledge of American concepts and practices. It manifests acquaintance with conditions affecting pregnancy in cultures and climes far removed from the teaching clinics of the British Isles. There is no provincialism, and many rare and astonishing cases are mentioned. Diagnostic details and therapeutics, however, as expressed in any of several domestic textbooks are far better for the purposes of American clinicians. This volume is not intended as a vade mecum, but rather as a survey and short discussion of all conditions subject to the twin specialty. This avowed purpose, perhaps, excuses it from the fuller annotations and references, which would authenticate or at least denote the sources of most of the statements made. This lack of substantiation gives the text an air of informality pleasant for browsing but inadequate for learning. There is a bibliography for each chapter, ranging from one item for miscarriage to fifty-four for tumors of the uterus and ovary.

There are a few line drawings in the chapter on transfusion and clyses. One shows the cistern and conductor for a Murphy drip. Another illustrates a table set up for collecting blood for a citrate transfusion, with a foot pump to suck air out of the receiving bottles and a donor with a cuff on his upper arm. The book is well bound and well printed.

La créatine: étude physico-chimique. By Jean Vague and Jean Duncan. 8°, paper, 256 pp. Paris: Masson et Cie, 1939. \$1.40.

This book seems a reasonably adequate review of the work on creatine and muscle metabolism, and the bibliography appears to be unusually complete.

NUMBER 16

MYCOTIC INFECTIONS OF THE SKIN*

OLIVER S. ORMSBY, M.D.

CHICAGO

THE cutaneous infections discussed in this paper include ringworm of the hands and feet, and several cutaneous conditions formerly classed as separate entities but now known to be due to yeasts or yeastlike micro-organisms.

RINGWORM INFECTIONS

Ringworm of the hands and feet was practically unknown in the United States until 1916, when Ormsby and Mitchell¹ reported a group of 65 patients, in all of whom fungi were demonstrated microscopically. This study included patients suffering with dyshidrosis and intertriginous eczema. Reports of cases had been made previously by Montgomery and Culver² (1914), by Hartzell³ (1915) and by Lane⁴ (1916). Some years later, intensive investigative work was instituted; it has been carried on throughout this country until the affection is now accorded a prominent place in the minds of both physicians and the laity. Its importance is undoubtedly exaggerated in the popular mind. The chief criticism at present from the dermatologist's standpoint is that the layman considers practically every cutaneous affection occurring on the feet and hands to be ringworm and treats it accordingly. Unfortunately, numerous physicians fall into the same error, but to a lesser degree. On account of the popular demand for self treatment, numerous proprietary articles are advertised and extensively sold, some of which inflict much damage. I believe that it is essential that the diagnosis of ringworm be confirmed microscopically in every case before treatment is instituted, and I have done this since the beginning. Unfortunately, many practitioners rely solely on the clinical symptoms for a diagnosis.

Clinical Description

The affection was early described by Whitfield and Kaufmann-Wolf. Each described three clinical

types: the acute vesiculobullous, the chronic intertriginous, secondary to the first type, and the chronic hyperkeratotic. In our original investigation we were able to confirm these findings. The initial lesions are vesicles and may be single, multiple, grouped or widely distributed. The vesicles are deep seated, slightly elevated or level with the surface and resemble boiled sago grains imbedded in the epidermis—this comparison is always made in so called "dyshidrosis." The content of the vesicle is serous unless contaminated by secondary infection. As a rule the early vesicles are not surrounded by redness. After several days to a week, the fluid is absorbed, and a brown macule remains. After desiccation, the roof of the vesicle becomes torn, exposing a red, smooth, shining surface surrounded by a collaret of scales. Sometimes the roof of the vesicle, instead of scaling, develops into a brown keratotic button 1 to 2 mm. thick. Beneath these keratotic lesions the usual red, shining surface is not found. It is through the multiplication of this type of lesion that the hyperkeratotic variety of the disease is produced. In acute cases the vesicles may be grouped, may become confluent and may form bullae. In extensive bullous cases the patients may be incapacitated for weeks. At times well defined, shiny red, circular areas, denuded of the corneal layer through desiccation and desquamation of groups of vesicles, develop in dry areas, such as in the center of the palm or on the sole or the arch of the foot. These patches may heal spontaneously, or new vesicles may continue to form around the periphery, with extension in one or several directions. The grouped vesicles may develop into a dry or moist, well-defined, eczematous area. In order of frequency of occurrence, the affected areas are the fourth interspace of the foot, the plantar surface of the arch and the tuberosity of the fifth metatarsus. At the base of the fifth toe, a fissure occupying both the interdigital and plantar areas is commonly present. Occasionally, similar fissures occur in the flexor folds of all the toes. In the fourth interspace, a white,

Portions of this paper have been published in the following journals: *Medical Record and Annals* (29:59-64, 1935); *Pennsylvania Medical News* (6:3, 1935); *Journal of the American Medical Association* (55:295-301, 1935); and *Journal of the Michigan State Medical Society* (37:135-140, 1938).

†Clinical professor, Department of Dermatology, Rush Medical College, University of Chicago; dermatologist, Presbyterian Hospital.

sodden, thickened, adherent mass of epidermis is of common occurrence and is produced through maceration of the exfoliated epidermis. This condition occasionally extends to other interspaces. In the keratotic variety, areas of keratoderma are formed, usually symmetrically and oftener on the soles. Occasionally, a diffuse palmar and plantar keratoderma develops. One of the cases studied in our original investigation had had symmetrical palmar and plantar keratoderma for thirty-two years. When the disease is complicated by secondary infection, there is often much swelling and edema of the undersurface of the toes, the contiguous portion of the soles and the intertriginous surface of the toes. Under these circumstances much tenderness and pain is experienced.

Ordinarily the chief subjective symptom is itching, which may be moderate to severe but is practically always present. In the widespread acute bullous cases, as well as those complicated with secondary infection, sensitiveness and pain are characteristic. Although in most cases the eruptive manifestations are limited to the feet and hands, occasionally well-defined, scaling patches of dermatitis may occur over the trunk and limbs, and in these the causative fungus can be found.

Diagnosis

The major portion of cases of dyshidrosis are examples of ringworm, like a great many cases formerly classed as intertriginous eczema, together with a certain percentage of cases of localized keratoderma of the hands and feet. An immediate diagnosis can nearly always be made by a microscopic examination of the roof of a sago-grain vesicle or of scales taken from the interdigital spaces, as well as from other scaling areas on the foot. The material to be examined is placed on a slide in a drop of a 10 to 20 per cent solution of sodium hydroxide. If the roof of the vesicle is used, it is placed with its undersurface up, the cover slip is placed over the preparation and the slide is gently heated until the preparation boils. Examination with a medium-powered lens reveals the fungus, which is seen as jointed mycelial filaments.

Disorders from which ringworm is to be distinguished are dyshidrosis, eczema, a resistant vesicular dermatitis of the palms and soles, a superficial vesicular eruption probably of infectious origin, an external irritant dermatitis and a pustular eruption of the palms and soles described below. Although the major portion of cases of what were formerly considered dyshidrosis are examples of ringworm, there still remain a number that can be regarded as dyshidrosis; these patients usually present a constitutional background, indicated

by circulatory changes, excessive sweating and so forth. In the resistant vesicular dermatitis, which is probably of toxic origin, the vesicles are usually deep seated, limited to the palms and soles, and do not involve the intertriginous areas. In practically all the cases that I have seen, the affection has been considered ringworm and treated as such without beneficial results. In the superficial vesicular type of infectious origin, similar areas of dermatitis may be observed on the glabrous skin; this finding is of diagnostic importance. In the external irritant type, the lesions are apt to be between the fingers and on the dorsum rather than on the palmar surface. In none of these is the ringworm fungus found microscopically.

Ringworm is readily distinguished from a pustular infection occurring on the palms and soles that has been described by Barber⁵ as pustular psoriasis, by Audry⁶ as an abortive form of *acrodermatitis continua*, and by Andrews, Birkman and Kelly⁷ as a recalcitrant pustular eruption of the palms and soles. This lesion is characterized by an exfoliative type of dermatitis beginning in the center of the palms, extending over the thenar and hypothenar eminences and at times covering the entire palm and palmar surface of the fingers. On the feet it occurs characteristically on the insteps, from which it may spread over the entire plantar surface. The interdigital areas, usually invaded by ringworm, are free. The early lesion is a small flat discrete pustule. Throughout the patch there are scattered pustules and crusts. These are more abundant at the margins. The course of the affection is characterized by periods of activity and partial quiescence. During the former, severe burning sensations occur. The lesions are resistant to treatment, and microscopic examination reveals no fungi.

Absence of fungi in the vesicles or scales taken from the feet is important from a diagnostic standpoint. It is much less significant in similar lesions taken from the palms. This is explained, as noted elsewhere, on the ground that in numerous cases of ringworm infection the palmar lesions are so-called "ide" eruptions, in which micro-organisms are rarely found.

Etiology

Men are affected oftener than women, and the cases have usually been diagnosed as dyshidrosis or eczema. The feet are affected much more frequently than the hands. Eczema marginatum not infrequently precedes the infection. Familial transmission occurs. Infection is more prevalent in warm weather, exacerbations occurring in the spring and autumn, but sporadic cases do occur during the winter months.

Various members of the genera, *Epidermophyton* and *Trichophyton*, are responsible for the affection. These organisms may lie dormant for long periods in calluses, under or about the nail or even in the superficial layers of epidermis between the toes. From these points reinfection occurs when heat and moisture develop in the warm season. Common sources of infection are dressing rooms, runways and shower baths in the athletic departments of schools and universities and in athletic and country clubs. The prevalence of mycotic infection of the feet and its increase in the gymnasiums of universities are well shown by a report by Legge, Bonar and Templeton⁸ from the University of California. At the beginning of the fall gymnasium work, 3105 freshman matriculants were examined; 51.5 per cent of the men showed clinical evidence of ringworm of the feet. At the end of the semester the same medical examiners found the proportion of involvement to be 78.6 per cent, an increase of 27 per cent. The infection was present in 15 per cent of woman matriculants at the beginning of the semester, and this had increased only 2 per cent at the end of that semester.

Treatment

The method of treatment depends on the type of eruption. When the eruption on the feet is acute, accompanied by vesicles and bullae together with secondary infection, hot soaks with a 1:2000 solution of potassium permanganate used two or three times daily are efficacious. In the interim between soaks, soothing ointments containing naphthalan or ichthylol or both may be employed. The following formula is useful:

Naftalan	10
Powdered starch	25
Zinc oxide	25
Petrolatum	<i>q. s. ad</i> 100

Ichthylol (2 per cent) may be substituted for naphthalan. When the acute stages have subsided, an ointment containing salicylic acid and benzoic acid, originally recommended by Whitfield, is efficient:

Salicylic acid	2
Benzoic acid	4
Petrolatum	<i>q. s. ad</i> 30

In our early work we used this or a 10 per cent chrysarobin ointment or suspension.

These preparations cause exfoliation. When this is complete, Hebra's unguentum diachylon alba may be employed at night, with a drying dusting powder containing magnesium carbonate in the morning. The formula for the latter is as follows:

Magnesium carbonate	4
Boric acid	4
Powdered talc	<i>q. s. ad</i> 30

This should be continued for several weeks, during which the salicylic acid and benzoic acid ointment mentioned above should be continuously employed as a prophylactic measure around and beneath the nails, and on calluses, if present. In the subacute and keratotic cases, the keratolytic ointment is advisable from the beginning. In the chronic intertriginous type, curettage, employed when the leathery whitened mass has been softened, hastens recovery. On the hands a zinc oxide and lime water lotion is advisable in the vesicular cases, together with the keratolytic ointment suggested for the feet, but reduced 50 per cent in strength. The formula for the lotion is as follows:

Sodium bichlorate	10
Zinc oxide	15
Powdered starch	15
Lime water	120
Rose water	<i>q. s. ad</i> 240

If the lesions are merely dry and scaling, the ointment will be sufficient.

In certain cases injections of trichophytin may be required. These should be used with caution, the initial doses should be small, and perhaps this method should be reserved for resistant and intractable cases.

Prophylaxis

Prevention on a large scale was practiced by Osborne and Hitchcock⁹ in the high schools of Buffalo. Through experimental work they demonstrated the efficiency of sodium hypochlorite as a preventive measure. They recommend the employment of rubber pans approximately two feet square containing a 1 per cent solution of sodium hypochlorite. These pans are placed in the shower rooms, and the students immerse the feet in one as they go into the bath and into another as they come out. In new athletic departments, wells are built in the floor of the corridor through which the students pass from the dressing room to the shower baths. The disease in the high schools in Buffalo was reduced to a minimum through these measures.

Sterilization of the shoes, socks and other articles of clothing, together with rugs and carpets that have been in contact with the feet of an infected patient, may be accomplished by formaldehyde fumigation. Ayres, Anderson and Youngblood¹⁰ recommend that this method be employed in the bedroom and bathroom of the affected patient. By the use of fumigation with a formaldehyde candle they demonstrated the effectiveness of

this procedure. Individual prophylaxis in country clubs is promoted by the use of wooden-soled sandals between the locker room and shower.

EPIDERMOPHYTIDS

These are eruptions produced by the local action of fungi brought to the skin by way of the blood stream from existing foci. The fungi are immediately destroyed on account of the existing allergy. They may also be secondary to infection of the hands and in the crotch. The ringworm micro-organisms are rarely present.

Ordinarily, the eruptions occur in association with acute and severe attacks of ringworm of the feet. Under these circumstances, the secondary eruption has acute manifestations and runs its course in a short time. In other cases, when the primary focus presents practically no recognizable symptoms, the secondary eruption may be of longer duration. The hands are the commonest site of this eruption, and the lesions may be vesicular or squamous. The vesicles may be superficial or deep, and the degree of the accompanying inflammatory reaction may vary. Occasionally, a more widespread eruption, occurring over the forearms, legs and elsewhere, may resemble pityriasis rosea or multiform erythema. Patches of dermatitis resembling eczema occasionally occur, and in rare cases the eruption may resemble a generalized exfoliative dermatitis.

Microscopic examination of the secondary lesion reveals no micro-organisms, whereas they may be demonstrated abundantly in the primary infection on the feet. An excellent experimental confirmation of these lesions was made by Peck,¹¹ who produced a ringworm infection of the feet in a human subject by inoculation with *Trichophyton gypsum*, which was followed after twenty-four days by a vesicular dyshidrotic type of eruption on the hands. The fungi were readily demonstrable in the primary infection on the feet, but the secondary eruption on the hands was free from organisms and was considered to be an epidermophytid.

Epidermophytids may be distinguished from the eruptions that they resemble by the location of the lesions and the accompanying ringworm infection present on the feet. The trichophytin reaction is positive and is a confirmatory finding. When the secondary eruption is eczematous, the trichophytin test is made by the patch method.

YEAST DERMATOSES (MONILIASIS)

Clinical Description

A number of cutaneous and mucous-membrane infections formerly described as entities have been

found to be due to yeast or yeastlike micro-organisms.¹² Two or more or all these eruptions may coexist in a given patient. Through experimental work all have been produced by inoculation of cultures taken from patients exhibiting the various types of dermatitis.

Paronychia. Mycotic paronychia presents a characteristic picture and has two forms, acute and chronic. The acute form occurs frequently in workers in fruit canneries and in other industrial laborers. The chronic form presents a typical appearance, described by MacLeod¹³ as a "pad or bolster-like swelling of the nail wall, which on being squeezed emits a bead of pus on the nail plate." This enlargement is most marked at the base of the nail and gradually tapers down on the sides toward the distal end of the nail plate. The degree of inflammation varies in different cases, and there is usually an associated dystrophy of the nail plate, owing to interference with the formation of the nail at the lunula. In acute cases, such as those described by Kingery and Thienes,¹⁴ seen in workers in fruit canneries, there is much swelling and pain, and often shedding of the nail.

Onychia. This monilial infection resembles the ringworm type. In the chronic form transverse ridges occur in the nail plate, which becomes opaque, thickened, discolored and brittle. Subungual keratoses are present beneath the lateral and distal portions of the plate, causing it to be raised from the bed.

Perlèche. In this condition, an inflammatory reaction occurs at the angles of the mouth, usually in children.¹⁵ It is characterized by a thickening and whitening of the epithelium, together with fissures. The infection sometimes spreads toward the center of the lip and over the glabrous skin in the immediate vicinity. The thickened epithelium, often likened to mother of pearl, is sometimes easily detached. Occasionally, a moderate degree of crusting occurs. The fissures are superficial and rarely bleed, and ulceration does not occur. A scaling dermatitis of seborrheic type sometimes occurs in the immediate vicinity.

Erosio-interdigitalis. This lesion occurs on the web of the fingers, usually in the third and fourth interspace.¹⁶ It may occupy all the interspaces, and it sometimes occurs between the toes. It is characterized by a shiny red area, surrounded by a collaret of scales; it may also be represented by an accumulated mass of sodden, moist, whitened epidermis. Vesicles are usually absent, although points on the reddened area may indicate former vesiculation. This form of moniliasis is exceedingly difficult to eradicate. In addition to the erosio type of lesion, a vesicular and papulo-

vesicular eruption occurs in the interdigital surfaces, with occasional maceration and fissuring.

Water-bed mycosis. This infection is characterized by the presence of herpetic-appearing vesicles with red areolas, together with pustules.¹⁷ These develop in a continuous water bath or on areas of the skin where moist dressings are applied for a long time. A frequent site is the abdomen, following laparotomy, when moist hot dressings have been employed. At times, when the inflammatory reaction becomes marked, redness, edema, weeping and crusting occur.

Glabrous-skin infections. On the glabrous skin a mycotic dermatitis is characterized by variously sized, well-defined, circular, red, scaling patches. By fusion, gyrate configurations are produced. Moist crusting patches, suggesting eczema, occasionally develop, and in widespread cases there occurs simply a dry dull-red scaling dermatitis. Patches begin with vesicles or vesicopustules, which rupture, leaving denuded red areas surrounded by rings of detached epidermis. These spread peripherally and by coalescence with others form the patches. New vesicles in the vicinity, which develop and undergo the above evolution, result in the invasion of large areas. In the crotch and beneath the breasts and in other intertriginous regions, the bottom of the cleft is usually fissured, and the skin in the involved area is shiny, light to dark red, presents some moisture and has scale-covered margins that are polycyclic in outline. When the anogenital region is involved, varying degrees of itching occur, for the relief of which scratching is practiced; this results in thickening, excoriations and fissuring of the skin. In the anal region the erosio type seen between the fingers is sometimes present.

Patches of dermatitis characterized by redness and vesiculation, scaling and crusting may also be found on the dorsum of the hands and on the forearms. Involvement of these areas frequently occurs in association with the paronychia seen in workers in fruit canneries.

Dermatitis seborrhoeica. The clinical description of this form of dermatitis will not be outlined, since it is familiar to all. The point of interest in this connection is the fact that a yeastlike organism—the pityrosporon of Malassez—was cultivated by MacLeod and Dowling¹⁸ from all types of this affection, and the disorder was reproduced by experimental inoculation. In their work they found it necessary to inject the cultures intradermally, or to rub them into lightly scarified areas, to reproduce the lesions.

Mucous-membrane infections. In addition to

thrush, which has long been known to be of mycotic origin, other forms of stomatitis and glossitis occur. Since there is no symptom complex characteristic of monilial infection, and since these organisms are sometimes found as saprophytes in such diseases as syphilis, some difficulty is encountered in recognizing the infections.

On the lip and buccal mucosa and on the mucous membrane of the pharynx and larynx, grayish-white membranous pellicles of varying dimensions are seen. These pellicles are translucent and usually easily detachable. They also occur on the tongue and gums. When the pellicles become more adherent, there is apparently more thickening, and when detached there are superficial erosions, presenting a clinical picture of leukoplakia.

On the buccal mucosa Engman and Weiss¹⁹ early described a lesion that occurred as a glistening white mat of filiform projections situated on a white macerated base.

On the tongue, Zeisler²⁰ described scroll-like patterns resembling geographic tongue. Robinson and Moss²¹ observed an acute form in which the anterior surface of the tongue was red and the papillae were edematous and eroded; they also noted a chronic form in which the papillae were absent and the surface of the tongue presented a smooth or slippery appearance like wet, red rubber. Miller and Morrow²² described a deep form in which a gummalike lesion developed in the soft palate in the tonsillar region. This lesion developed acutely and caused perforation of the soft palate.

Etiology

Cutaneous and mucous-membrane mycotic infections may occur at any age and in both sexes. Paronychia is at times an occupational disease induced in cases described by Kingery and Thienes¹⁴ by contact with fruit juices in cannery workers, and in the cases described by Sutherland-Campbell²³ by contact with orange juice. It frequently occurs in women who handle sugar, such as those employed in confectionery factories, and in pastry cooks. Diabetes is occasionally a predisposing factor. In the erosio type, constant immersion of the hands in water, a condition imposed in washerwomen, is effective, and constant wet dressings constitute the predisposing factor in the waterbed type. Infection of the skin in infants frequently comes from oral and intestinal thrush, and in adults not infrequently from the stools. The organism most frequently found is *Monilia albicans* (*Oidium albicans*). Cryptococci, the pityrosporon of Malassez and other yeastlike organisms are also concerned in the production of these mycoses.

Diagnosis

The major portion of cases of mycotic infection of the skin due to monilia and related organisms present sufficiently characteristic symptoms to be recognized. A microscopic examination in all cases is essential. Scrapings from the lesions are mounted on a slide in a 10 to 25 per cent solution of sodium hydroxide, over which a cover slip is applied, and the preparation is gently heated. The organism shows plainly and presents the following characteristics with a medium high-power objective: mycelium and sporelike bodies are seen; the myceliums are more delicate and less refractile than those of the ringworm fungi, and septums are rarely demonstrable; oval sporelike bodies, with buds attached to the ends, are also present. In young cultures the organism appears chiefly as round or oval cells, which multiply by budding; in old cultures hyphae develop.

Treatment

Oral thrush in infants responds well to swabbing with a 1 per cent solution of gentian violet, together with mild alkaline mouth washes. For superficial lesions of the mucous membranes of the mouth and vagina, a 3 per cent solution of gentian violet used on a swab twice daily, is efficient. Alkaline mouth washes for the oral cavity and a douche containing a 1:2000 solution of potassium permanganate for the vagina facilitate recovery. For the deeper lesions on the oral mucosa surgical excision, roentgen rays and potassium iodide internally may be necessary.

Paronychia responds quickly to local applications of a 5 per cent suspension of chrysarobin in chloroform. This was originally recommended by Morrow and Lee²⁴ for the treatment of chronic paronychia, before moniliasis had been recognized. In the erosio type, which is resistant, the parts should be kept dry. The local application of a 5 to 10 per cent solution of chrysarobin or tincture of iodine is valuable. In the water-bed type, the suspension of wet dressings, together with the application of zinc oxide and lime water lotion, and the 10 per cent naftalan or 2 per cent ichthyol ointment previously described, soon relieves the condition.

In the intertriginous type, occurring especially beneath the breasts and in the crotch, painting with

a 3 per cent solution of gentian violet is very efficacious. When much inflammatory reaction is present, a preliminary treatment for several days may consist in soaking the parts twice daily with a hot 1:2000 solution of potassium permanganate, dressing the parts in the interim with the naftalan ointment previously mentioned.

In perlèche, Finnerud¹⁵ found the local application of an 8 per cent solution of silver nitrate to be effective. This application may be repeated at intervals of three or four days. Prophylaxis, necessary when this condition occurs in epidemics, consists in the use of individual drinking cups and towels, careful sterilization of the utensils used by the patients, and the avoiding of direct contact.

THE DEVELOPMENT OF THE CONCEPT OF HYPERTENSIVE HEART DISEASE

DAVID DAVIS, MD,* AND MAX J. KLAINER, MD†

BOSTON

GENERAL recognition of the importance of hypertensive heart disease is comparatively recent. Yet more than a century ago physicians were familiar with cardiac hypertrophy unassociated with valvulitis or heart failure, and they devoted considerable discussion to its clinical and post mortem features. In 1930, Weiss¹ traced the historical development of the concept of essential hypertension, but since his study did not deal primarily with the hypertensive heart, a review of this aspect of the problem is of interest.

Corvisart² in 1812 presented a list of factors of possible significance in the production of cardiac hypertrophy not due to valvular disease, but it remained for Bertin,³ about twenty years later, to investigate their relative importance. Bertin appreciated the importance of mechanical obstruction as a cause of hypertrophy, but was unable to explain all forms of cardiac enlargement on this basis. Consequently he proposed the theory that cardiac hypertrophy was due to the "irritating" stimulus of an increased quantity of arterial blood in the chambers of the heart.

Hope,⁴ his English contemporary, however, maintained that cardiac hypertrophy could be explained on the basis of mechanical obstruction alone. In his textbook, published in 1832, he speaks of the effects of a "perinatural" pressure of blood on the heart.

According to the foregoing opinions on the mode of formation of hypertrophy, it will be apparent that every circumstance capable of increasing the action of the heart for a sufficient length of time may be a cause of hypertrophy. These circumstances may be either, first, of a nervous or, second, of a mechanical nature.

The latter class embraces all physical causes which can either accelerate or obstruct the circulation, and thus occasion a perinatural pressure of blood upon the heart.

The physical causes which obstruct the circulation are very numerous. They comprise smallness of the aorta, whether congenital or acquired, dilatation of the aorta, inequalities of its internal surface, all diseases of the valves of the heart which either contract their apertures or impede their movement, adhesion of the pericardium, all affections of the chest that obstruct the circulation through the lungs, as peripneumony, acute, or chronic, empyema, hydrothorax, chronic ca-

tarrh, emphysema. As an obstacle of the circulation operates on the heart in a retrograde direction, the cavity situated immediately behind it is the first to suffer from its influence. Accordingly all the impediments seated in the aorta, its mouth or the arterial system, act primarily on the left ventricle, which, being likewise exposed to the heaviest burden when the circulation is accelerated, has to conflict against a greater variety of exciting causes of hypertrophy, than any other cavity of the heart.

Other writings of this period also give the impression that the existence of an extracardiac factor in the causation of hypertrophy was suspected, the two observations that did most to nurture this suspicion were the frequent association of apoplexy and enlargement of the left ventricle, and Bright's discovery of the association of kidney disease and cardiac hypertrophy. The following statements by Bertin³ and by Hope⁴ indicate how well the first observation was appreciated.

Nothing is better demonstrated in physiology, in the present day, than the influence of the left heart on the circulation of the encephalon, we might, consequently, advance *a priori* that one of the immediate consequences of hypertrophy of the left ventricle would be a predisposition to apoplexy, to encephalitis, and, in fact, to all the cerebral irritations.

Since the researches of the present day have demonstrated that even a slight thickening of the walls of the heart constitutes a morbid state, and have unfolded to view the connection subsisting between that state and a train of symptoms formerly either wholly overlooked or attributed to other causes, instances of apoplexy supervening upon hypertrophy have been so frequently noticed, that the relation of the two as cause and effect is one of the best established doctrines of modern pathology.

Perhaps more important was the observation by Bright⁵ in 1836 that cardiac hypertrophy was frequently associated with contracted kidneys. In his paper, entitled "The Tabular View of the Morbid Appearance in 100 Cases Connected with Albuminous Urine," he established conclusively that there is a relation between kidney disease and cardiac hypertrophy.

The first circumstance which strikes the mind, is the extent and frequency to which the derangement of one organ is connected with the derangement of several others, yet we are not at liberty to assume that the disease of the kidney has been the primary cause on which the depression of the rest depended. It may be that some other organ has first suffered, and that the

*Junior visiting physician Beth Israel Hospital, instructor in medicine Harvard Medical School.

†Assistant in medicine Beth Israel Hospital, member Cardiac Clinic Massachusetts Memorial Hospitals.

kidneys, together with the rest, have become involved. . . . I am inclined to believe that the kidney is the chief promoter of the other derangements. . . . The obvious structural changes in the heart have consisted chiefly of hypertrophy with or without valvular disease; and what is most striking, out of fifty-two cases of hypertrophy, no valvular disease whatsoever could be detected in thirty-four; but in eleven of these thirty-four, more or less disease existed in the coats of the aorta; still, however, leaving twenty-two without any probable organic cause for the marked hypertrophy generally affecting the left ventricle. This naturally leads us to look for some less local cause, for the unusual efforts to which the heart has been impelled, and the two most ready solutions appear to be, either that the altered quality of the blood affords irregular and unwonted stimulus to the organ immediately; or, that it so affects the minute and capillary circulation, as to render greater action necessary to force the blood through the distant sub-divisions of the vascular system.

Although the clinicians of this period were familiar with nonvalvular hypertrophy as a clinical and pathological entity, they did not clearly understand its relation to cardiac failure. Bertin, for example, contended that it had nothing to do with the signs and symptoms of heart failure, that these were due to other cardiac changes such as valvular lesions, and that uncomplicated cardiac hypertrophy was characterized by evidence of increased cardiac activity and energy of the circulation rather than by signs of failure. To this, Hope also took exception. He agreed that it might be true of the pure uncomplicated form of cardiac hypertrophy, before embarrassment of the circulation had occurred, but not later:

. . . the truth I believe to be, that the very same energy of the circulation which gives rise to active hemorrhage, apoplexy, etc., causes, as its next effect, engorgement of the arterial capillary system; the necessary consequence of which is serous infiltration and more or less of all the other symptoms indicative of retardation of the circulation.

Thus Hope pointed out a connection between nonvalvular cardiac hypertrophy and heart failure, but he had little understanding of the nature of heart failure, believing as he did that it was a consequence of the effects of hypertrophy on the peripheral capillary system. A clear description of the nature of heart failure did not appear until the writings of Bamberger⁶ in 1857.

Bright's conception of renal disease as the primary focus of a general disturbance stimulated further observation that finally led to the recognition of the following separate clinical entities: essential hypertension, diffuse atherosclerosis and primary renal disease with hypertension. Wilks,⁷ in 1852, called attention to the occurrence of thickened and tortuous arteries in Bright's disease, and also pointed out that albuminuria was not invari-

ably present. He thus raised the possibility that other conditions might precede the loss of kidney function. At this time Johnson⁸ held that it was the small vessels of the body, including even those of the skin, that were contracted and thickened in nephritis. He proposed the thesis that the toxic blood was unable to nourish the tissues; that the minute arteries resisted the passage of this toxic blood and that, as a result of this resistance, both cardiac and arterial muscle tissue became hypertrophied. Traube⁹ also maintained that in renal disease an increased resistance to renal blood flow resulted in an abnormal tension in the aortic system and hypertrophy of the left ventricle. In his discussion of kidney disease, Traube states:

I believe that the cause for the increase in aortic tension is the abnormal resistance which results from the inflammation of the kidneys and which obstructs the outflow of blood from the aorta through the vessels of the kidney. . . . This increase in tension in the aortic system caused by the decrease in the outflow of blood from the aorta, is itself the cause of left ventricular hypertrophy. . . .

Both Johnson and Traube agreed with Bright that the cardiac and vascular changes were secondary to the primary disturbance of kidney function.

The next important contribution to the subject was that of Gull and Sutton¹⁰ in 1872. After an exhaustive study, they concluded that there was a primary disease of the vascular system throughout the body characterized by a diffuse hyaline fibrosis, and that this condition was independent of renal disease. Their proof that marked cardiac hypertrophy and widespread capillary fibrosis could exist with varying degrees of nephritis stimulated the search for factors other than kidney disease as the cause of the cardiac hypertrophy. Further progress in the differentiation of hypertensive states had to await the development of clinical instruments for the measurement of blood pressures.

Mahomed,^{11, 12} using a crude method for determining blood pressures, pointed out for the first time in 1874 that there was a condition in which the blood pressure was elevated before there was any albuminuria or evidence of renal disease. He also attached great importance to the circulatory system in the origin of this disease, and maintained that the disease in the arterial system was really the cause of the albuminuria, rather than that the albuminuria was the cause of the vascular fibrosis.

Von Basch¹³ soon showed that elevated blood pressures were common, and with the aid of more precise instruments he accumulated measurements and observations that have formed the basis of the modern concept of essential hypertension. He also

observed that the blood pressure may be normal or elevated in severe circulatory failure, and that although palpation of the larger arteries may reveal no evidence of arteriosclerosis, the smaller vessels may be the site of considerable change. On the other hand, he did not understand the relation between hypertension and arteriosclerosis, for he believed that the blood pressure was invariably high in the presence of arteriosclerosis and that it was an accurate clinical index of arterial disease.

The clinical state of hypertension then drew the attention of physicians, including Huchard,¹¹ Sawada,¹² Allbutt¹³ and Pal.¹⁴ Huchard did not carefully distinguish between diffuse arteriosclerosis, as such, and essential hypertension, but Sawada, in 1904, demonstrated that the blood pressure was often normal in the presence of extensive arteriosclerosis. Influenced by this observation and by Mahomed's concept, Allbutt fostered the theory that hypertension was an independent condition. He clearly differentiated arteriosclerosis of the larger vessels from arterial hypertension or, as he called it, "hyperpiesia." Volhard and Fahr¹⁵ re-investigated kidney diseases in 1914 and differentiated vascular nephrosclerosis from primary renal disease. Primary hypertension, however, was not considered a separate clinical condition for a long time, although a few outstanding clinicians advocated this new concept.

While these relations were being clarified, the condition of the heart in patients with elevated blood pressures received increasing attention. Allbutt did much to crystallize the thought that hypertensive heart disease was a distinct clinical entity, with a course differing from that in nonhypertensive cases. He believed that the hypertensive heart failed when the strength of its hypertrophied muscle fibers was exhausted, and that after a certain degree of hypertrophy the heart had little capacity for recovery. Krehl¹⁶ and Huchard,¹⁴ on the other hand, stressed the importance of cardio-sclerosis or disease of the coronary arteries in the production of this type of heart failure. In this country, Fahr¹⁵ was one of the first to appreciate the clinical significance of hypertensive heart disease. He maintained that heart failure unassociated with chronic valvular disease was most frequently of this origin. Christian²¹ also stressed the importance of this form of heart disease.

In 1928, Bell and Clawson²² pointed out the high incidence of coronary sclerosis in hypertensive patients, and Levine and Brown²³ called attention to the frequency of hypertension in patients with coronary thrombosis. Murphy, Grill, Pessin and Moxon,²⁴ studying the same problem, found that more than 25 per cent of their cases of hyper-

tensive heart failure had gross coronary involvement. Thus, it became established that hypertensive heart disease was associated not only with cardiac hypertrophy but also with an increased incidence of coronary atherosclerosis.

Difference of opinion, however, concerning the relative importance of these factors still prevailed. We reinvestigated the problem, by comparing the anatomical findings in hypertensive and non-hypertensive patients with angina pectoris and congestive failure, and found that both angina pectoris and congestive failure occurred with less coronary sclerosis in hypertensive patients.²⁵⁻²⁶ Severe coronary disease, with occlusion of one or more vessels, was present in 90 per cent of normotensive patients with angina pectoris, whereas in the hypertensive group, coronary disease of this magnitude was present in only 55 per cent. A corresponding difference in the incidence of myocardial infarction in both groups was also demonstrated. Likewise, in patients with congestive failure, severe coronary disease was invariably present in the nonhypertensive cases, but was found in only 53 per cent of the hypertensive group. It appeared established, therefore, that factors other than coronary disease are also important in the mechanism of both angina pectoris and congestive failure associated with hypertension. Two factors known to be present in this condition are cardiac hypertrophy and increased cardiac work.

It has been suggested that cardiac hypertrophy interferes with nutrition of the heart muscle, because the number of capillaries remains unchanged in spite of the increase in muscle mass²⁷ and because oxygen diffusion is impaired in the hypertrophied muscle fibers.²⁸ Increased cardiac work is known to be important in angina pectoris associated with thyrotoxicosis and anemia. These two factors are present in most patients with hypertension, and their relative importance is probably related to the magnitude of the hypertrophy and the degree of hypertension present.

Since it was first demonstrated that atherosclerosis was increased in essential hypertension, many have held that atherosclerosis is due to the effects of the elevated tension on the walls of the arterial system. This concept appeared to be in harmony with the increased occurrence of atherosclerosis with age. Our²⁹ studies, however, have shown that the atherosclerosis found in patients with essential hypertension is unrelated to the elevated tension itself. The coronary arteries of patients with marked hypertension of renal origin, for example, did not show the increased incidence of atherosclerosis found in patients with essential hypertension. In patients with renal hypertension,

the degree of coronary sclerosis was the same as that in controls of the same age and sex. Likewise no relation was found between the severity of hypertension—as evidenced by blood-pressure levels and heart weights—and the degree of coronary sclerosis. These findings are in harmony with the experimental studies of Goldblatt,³⁰ who observed no increased atherosclerosis in his dogs in which experimental hypertension was induced.

* * *

It appears, then, that in the pathogenesis of hypertensive heart disease there are two coincidental yet independent phenomena. The first is the development of elevated blood-pressure levels that in time lead to cardiac hypertrophy and increased cardiac work, both of which demand additional nourishment for the myocardium. The second is the increased tendency toward atherosclerosis, especially of the coronary vessels, which interferes with cardiac nourishment and function.

PULMONARY FIBROSIS IN RAYNAUD'S DISEASE*

HARRY LINENTHAL, M.D.,† AND ROBERT TALKOV, M.D.‡

BOSTON

RAYNAUD'S disease is usually defined as an intermittent spasm of the digital arteries brought on most frequently by exposure to cold or by emotional strain. It is always symmetrical in its manifestations.

The disease is not always confined to the digital arteries. Cases of Raynaud's disease have been reported in which intermittent blindness as well as transient hemiplegias occurred, presumably due respectively to spasm of the retinal and cerebral vessels.¹ As Raynaud's disease progresses, nutritional disturbances of the skin, manifested by fibrosis, take place. These sclerodermatous changes are not confined to the hands, but may frequently involve the skin of the ears, nose and face.

The manifestation of nutritional skin changes

and fibrosis over areas other than the skin of the fingers makes it seem probable that the vasospasm that causes Raynaud's phenomenon may also occur in the small arteries of the skin. The absence of acute circulatory phenomena in the skin may be due to the greater anastomosing circulation in the skin as compared with that in the digital arteries. However, when alterations in the walls of the small vessels take place and there is a permanently insufficient blood supply to the skin, the normal skin degenerates and is replaced by connective tissue.

The question naturally arises whether the same nutritional and subsequent fibrotic changes in the skin may not also occur in other organs of the body secondary to vascular changes similar to those in the digital arteries.

The following cases started with the typical phenomenon of Raynaud's disease, developed sclero-

*From the Medical Service, Beth Israel Hospital.

‡Resident in medicine, Beth Israel Hospital.

derma and showed pulmonary fibrosis in the absence of any other known etiologic factor. The fibrosis of the lungs ran a course much more rapidly progressive than is usually seen in other types of pneumofibrosis.

CASE REPORTS

CASE 1 Mrs S A, a 45-year-old woman had noted for about 12 years that on exposure to cold the middle fingers of both hands became dead white, then cyanotic and then red. This was associated with painful tingling and numbness of the finger tips. The attacks increased in frequency and severity, and after about 5 years the skin of the fingers and hands became permanently cyanotic and hard, the fingers could not be fully extended, the terminal phalanges were narrow and shortened and the nails were curved because of atrophy of the finger pulps. These sclerodermatous changes later involved the skin of the face which became smooth, firm, somewhat expressionless and diffusely pigmented. The feet were affected to a slighter degree. All arterial pulsations could be felt, in both the hands and the feet.

About 10 years after the onset of the disease during an examination because of a mild upper respiratory infection dullness accompanied by numerous fine crackling rales at the base of the left lung was found. The breath sounds were bronchovesicular, and there was increased fremitus to the spoken and whispered voice. The heart was displaced to the left. These signs had not been present on examination three years previously. The patient stated that for some time she had had dyspnea on exertion but no other symptoms. The past history revealed no etiologic factor for these pulmonary findings other than Raynaud's disease. The patient had had no cardiac disease and no history of unusual or repeated pulmonary infections or exposure to dust. Repeated examinations of the sputum were negative for tubercle bacilli and other significant organisms. Roentgenograms of the lungs showed increased markings and diffuse mottling in the lower half of both lung fields, and displacement of heart and mediastinal contents to the left owing to atelectasis.

During the next year, the dyspnea, cyanosis and x-ray changes increased progressively, so that in the fall of that year the patient had constant respiratory distress, even at rest. An acute episode of severe respiratory embarrassment pain in the right chest and marked cyanosis made hospitalization necessary. On admission the respirations were 70, the patient had slight fever, and there were many moist rales in both lungs from the angles of the scapulas down. The roentgenogram showed a pneumonic process at the right base. Oxygen therapy was started immediately and was continued until death, 46 days later. During the first few days the patient was reasonably comfortable while in the tent but she developed extreme dyspnea and cyanosis when taken out for even a short time. Later, however, respiratory embarrassment and cyanosis increased progressively, even while the patient was in the oxygen tent. Death was apparently due to asphyxia. Permission for a post mortem examination was not obtained.

CASE 2 Mrs B F, a 39-year-old woman, entered the hospital complaining of intermittent attacks of 13 years duration during which the skin of the face, abdomen and hands became blue, especially when exposed to cold. She also experienced pins-and-needles' sensations in her fingers. These attacks had increased in frequency during the several months prior to entry. For a few years the

patient had noticed shortness of breath and palpitation on exertion but had no other complaints.

Physical examination showed cyanosis of the face, tongue and hands especially the finger tips. There was some atrophy of the skin over the distal phalanges which appeared shortened. The fingers were stiff on attempted motion. Scattered under the skin of the hands and fingers were small irregular deposits of whitish material, which on chemical examination proved to be calcium salts. There was minimal narrowing of the retinal arteries. The blood pressure was 140/80. Examination of the heart, lungs and abdomen revealed no abnormalities. All laboratory determinations were within normal limits.

Roentgenologic examination of the chest showed exaggerated markings in the lower halves of both lung fields, the hilar regions were greatly increased in width and density, and the pulmonary conus appeared prominent. Roentgenograms of the hands showed partial destruction of the distal ends of some of the terminal phalanges and small calcified bodies in the soft tissues that were consistent with the diagnosis of calcinosis circumscripta. Roentgenograms of the feet, skull, femurs and genitourinary tract showed no deviations from the normal.

During the following months the symptoms progressed, and dyspnea and cyanosis were severe enough to require constant bedrest. During the few weeks prior to death, scattered moist rales developed at both bases, and slight edema of the ankles became evident with no other signs of cardiac failure. Digitalization was without effect on the edema, rales or dyspnea. The patient died from respiratory failure 20 months after admission. Permission for a post mortem examination was not obtained.*

CASE 3 Mrs E S, a 30-year-old woman had noticed for 3 years before admission to the hospital that her hands, fingers and feet felt numb and cold and turned blue on exposure to cold. The fingers, hands, elbows, knees and ankles were sore and stiff and the skin was noticeably dry. For 8 months the patient had experienced easy fatigability, anorexia and lack of ambition. Examination revealed stiffness of the wrist joints and thickened fingers, fixed in flexion. The skin of the fingers, hands and forearms was cold, dry, shiny and brownish; the finger tips were reddish purple. Similar changes were present about the ankles and toes. The skin over the face, neck and anterior chest was indurated and dry. Pulsations were palpable in all the peripheral vessels. The blood pressure was 142/94. The heart and lungs were normal except for a vital capacity of 1600 cc.

Roentgenologic studies showed marked osteoporosis of the bones of the wrists and hands. The chest plate revealed moderate increase in width and density of the hilar regions, and slight mottling and diminished radiance at both bases.

Bilateral dorsal sympathectomy was performed, after which the patient developed a mild pneumonic process at the right base, which subsided in a few days. Following a bilateral lumbar sympathectomy, she developed a pulmonary embolus in the left lower lobe. The symptoms of

stage of her illness began with chills, fever and cyanosis at both lung bases. The patient also developed a pericardial friction rub and died in a few days. Permission for post mortem examination was not obtained.

*We are indebted to Dr. Louis S. Liver for the history of Case 2 after the patient left the hospital and to Dr. Samuel L. Cargill for his permission to report Case 3.

These 3 cases have similar histories. They all started with typical manifestations of Raynaud's disease that continued for several years. Then nutritional changes of the skin occurred, and scleroderma developed; some time later the patients began to complain of dyspnea on exertion. Coincidentally, roentgenologic examinations showed fibrosis in the bases of the lungs. In no case were there any factors that would explain the etiology of the pulmonary condition. None of them had evidences of cardiac disease; there was no history of repeated pulmonary infections, or of exposure to agents that might cause pulmonary fibrosis. The rapidity with which the fibrosis progressed and the severity and rapid development of the respiratory difficulty were very unusual, and were not typical of any of the usual types of progressive pulmonary diseases. All three patients died within three or four years after the onset of the dyspnea. In the last case, an intercurrent infection was the immediate cause of death.

Even in cases of extensive fibrosis of the lung due to silicosis, the progress is not so rapid, nor is the dyspnea so marked as that seen in these cases.

We were unable, unfortunately, to get post-mortem evidence that vascular changes in the lungs were responsible for the pulmonary fibrosis in the above cases. However, the rapid development of the changes in the lungs and the marked dyspnea and cyanosis existing together with Raynaud's disease and scleroderma suggest that the pulmonary fibrosis was due to vascular disease in the lungs, similar to that which takes place in the skin in Raynaud's disease.

Matsui² published complete post-mortem findings in 6 cases of diffuse scleroderma that were clinically similar to the cases reported above with respect to the hands and fingers. He found typical changes in the small vessels of all the organs, with secondary fibrosis of the parenchyma. Thus the changes in the small branches of the pulmonary artery, similar to those found in the digital arteries, were accompanied by extensive fibrosis of the lungs. The changes in the vessels were characterized by hypertrophy of the musculature of the

media and fibrosis and thickening of the intima, with great narrowing of the lumen—changes characteristic of Raynaud's disease.

The situation in Raynaud's disease is thus analogous to that in thromboangiitis obliterans. Until recently the latter was regarded as a disease confined to the blood vessels of the extremities. In the last few years, however, after attention had been called to the fact that thromboangiitis obliterans may be a generalized vascular disease,³ numerous reports of cases of involvement of the systemic arteries by the disease have appeared in the literature. A recent report from the Mayo Clinic⁴ noted the occurrence of thromboangiitis obliterans in the coronary arteries, as well as a case of the disease in the pulmonary artery.

Raynaud's disease, as the foregoing histories suggest, should be regarded, not as being limited to the small arteries of the extremities, but as involving the small arteries of the lungs and possibly of other organs of the body. It is also possible that an occasional obscure case of pulmonary fibrosis is an exceptional example of Raynaud's disease without the typical manifestations in the digital arteries.

SUMMARY

Three cases are reported, all starting with typical manifestations of Raynaud's disease. In the course of several years, scleroderma developed, with subsequent fibrosis of the lungs of unknown etiology. The suggestion is made that the pulmonary fibrosis was secondary to changes in the small vessels of the lungs as a part of Raynaud's disease, and that this disease is therefore not limited to the digital arteries or the arteries of the extremities, but may involve the arteries of the lungs and possibly those of other organs of the body.

CLINICAL NOTES

MENINGOCOCCEMIA

LEON E. KATTWINKEL, MD*

WEST NEWTON, MASSACHUSETTS

MENINGOCOCCEMIA is a relatively rare cause of intermittent fever accompanied by a rash and may present a real problem in diagnosis. This fact, as well as the demonstration that small doses of sulfanilamide are inadequate in preventing a recurrence of temperature and rash, makes it seem worth while to add one more case to the growing literature of this disease, which in the past has been considered a clinical rarity.

The disease was first described by Solomon¹ in 1902. In 1931, Bunn and Fothergill² pointed out that the majority of cases had been reported in the foreign literature, only 19 being found in American journals. They reported a case in a child eight years old, who recovered after treatment with antimeningococcus serum. Since that time, each year four or more reports have appeared dealing with both the clinical and laboratory aspects of the disease.

Heinle³ points out that there are two main types of meningococcal septicemia. The first is acute and fulminating and is invariably fatal, the second is chronic and lasts many months, with spontaneous recovery in many cases. The latter are fortunately in the majority. Lambie⁴ reports a case that ran a self limited course of three and a half weeks. He believes that meningitis should be regarded as only one metastatic lesion of meningococcal septicemia.

An excellent clinical description is given by Carbone and Campbell,⁵ who report 33 cases from the literature and 3 of their own. The symptoms and signs in the order of frequency are rash, intermittent fever, arthralgia, chills, headache and myalgia. They point out, as do most writers on the subject, the difficulty of growing the organism, even in enriched mediums.

The fever differs from malaria in that the daily peak does not occur at the same hour.⁶ As a rule the patients do not appear toxic or acutely ill.⁷ When first seen, the patient is thought to be suffering from ordinary grippé with general malaise, fever and myalgia. Shortly afterward, in from one to three days, a macular rash appears, usually on the extremities. Although it is pink at first, it may later be purplish or even hemorrhagic. There may be arthralgia.⁸ The fever, rash and general

ized symptoms disappear in twenty four to forty-eight hours, only to recur at intervals of from one to four days. In the early stages, the disease is confused with measles, typhoid fever, Rocky Mountain spotted fever and malaria. Later the differentiation from gonococcemia may become difficult.

The chief laboratory problem is growing the organism from the blood stream. Serum agglutination tests may be necessary.⁷ The complement fixation test may be positive,⁶ a feature that is rarely mentioned in the literature.

The chief complication is meningitis, which usually occurs late. Endocarditis occurs in 10 per cent of the cases. Nephritis may develop, but is rare. Epididymitis is a not infrequent complication in men.⁷ The arthritis may go on to articular destruction and ankylosis.⁸ The Waterhouse-Friderichsen syndrome, owing to acute bilateral supratentorial apoplexy, is often caused by meningococcal septicemia, but is usually seen only in infants and young children.⁹

Until the advent of chemotherapy, treatment was limited to the use of antimeningococcus serum⁶ and fever therapy.¹⁰ However, in the last few years, dramatic cures have been reported with sulfanilamide¹¹ and sulphyridine. Dimson¹² favors the latter because of its quicker action and because a smaller dosage is necessary.

CASE REPORT

A 22-year-old unmarried woman while on Cape Cod on June 10, 1940, removed several ticks from her body, none of which had burrowed under the skin. Thirty-six hours later she had general malaise, chilliness and a temperature of 101°F, which lasted for 2 days. On June 16, 6 days later, the temperature again reached 101°F, and a maculopapular rash, which was hemorrhagic in spots, was present on the extremities. She was not toxic, and the physical examination was otherwise negative. On June 18, the rash was fading and the temperature was normal. On June 19, the temperature reached 102°F, general aching was present, and the patient complained of pain in the right knee. On June 20, the rash was more pronounced and had spread somewhat over the body. The macules could be blanched by pressure and were slightly raised and tender. The patient was referred to the Newton Hospital.

On June 20, the Widal test, Weil-Felix reaction, agglutination test for undulant fever and blood Hinton test were negative. The blood smear showed no plasmodia. A blood culture taken on June 22 when the temperature was 102°F, showed gram negative intracellular diplococci that fermented glucose but would not grow in milkose. At this time, a history of leukorrhea, present for several years, was obtained. The patient admitted possible exposure to a gonococcal infection, and a tentative diagnosis of gonococcemia was made. She was started on 40 gr of sulfanilamide a day. Vaginal smears on June 26 and 30 were negative for gram negative intracellular diplococci. On June 26, there was a recurrence of fever, with chilliness and rash, and localized swelling and redness of the right 2nd and 3rd metacarpophalangeal

*Preceptor Tufts College Medical School visiting physician Newton Hospital.

joints. Complement-fixation tests for gonococcus, done on June 27 and 28, were positive. Organisms were again grown from the blood stream on June 25. These did not grow on maltose for 10 days, after which fermentation was present, thereby establishing the diagnosis of meningococcemia. She was discharged after 6 days of sulfanilamide therapy.

On July 8, there was a recurrence of temperature of 103°F., with rash, sore throat and aching of the back and knees. The patient was readmitted to the hospital by Dr. Lewis I. Pilcher, and was seen by Dr. Chester S. Keefer, who made a diagnosis of chronic meningococcal septicemia and advised intensive sulfanilamide therapy, with a blood level of not less than 10 mg. per 100 cc. This was carried out for 7 days. On July 18, a blood culture was negative, and on July 20 the patient was discharged.

When seen on August 21, the patient had had no recurrence and was clinically well.

This case was characterized by intermittent fever, arthralgia, a macular rash and very little evidence of toxicity. The diagnosis was delayed by the slow growth of the organism in maltose and the positive gonococcal complement-fixation test, coupled with a history suggestive of venereal disease. The question of Rocky Mountain spotted fever was raised because of the history of tick exposure. Haverhill fever was considered before blood cultures were positive. Sulfanilamide in daily doses of 40 gr. for six days was inadequate for complete cure, which was accomplished by seven days of intensive sulfanilamide treatment.

SUMMARY

A case of meningococcemia that at first suggested gonococcemia because of the history and positive complement-fixation test is presented. Small doses of sulfanilamide were therapeutically ineffective, but the drug in doses sufficient to maintain a blood level of 10 mg. per 100 cc. for seven days effected a permanent cure.

PNEUMOCOCCAL MENINGITIS SUCCESSFULLY TREATED WITH SULFATHIAZOLE AND ANTIPNEUMOCOCCUS SERUM*

J. M. RUEGSEGER, M.D.,† AND
MORTON HAMBURGER, M.D.‡

CINCINNATI

IN 1939, Fosbinder and Walter¹ described two new derivatives of sulfanilamide that gave promise of clinical usefulness. Since that time, sulfathiazole has been reported as being of value in the treatment of pneumococcal and staphylococcal infections, and this has been confirmed in our own experience. Recently, we have had an opportunity to administer sulfathiazole to a patient with pneumococcal meningitis with very encouraging results. Because a review of the literature fails to disclose a similar instance of its use, we are reporting the case.

CASE REPORT

A. L., a 50-year-old man, was admitted to the Ophthalmic Service on June 28, 1940, complaining of inability to see out of the left eye. He had had four abscessed teeth removed on May 5, 1940. Following the extraction, he felt quite well until he was stricken with pain in the left eye 3 days prior to admission. Examination at that time revealed an exquisitely tender eye, with pus in the anterior chamber. A diagnosis of acute purulent endophthalmitis, probably metastatic, was made. Expectant treatment failed to bring relief, and an enucleation was performed on June 30. No evidence of orbital infection was noted at operation. The postoperative course was satisfactory and without fever until the evening of July 6, when the patient complained of pain in the right side of the neck; the temperature at this time went to 103°F. by rectum. The sensorium became clouded, and the patient soon became very unco-operative, although not comatose.

Lumbar puncture disclosed a clear fluid under slightly increased pressure; it contained 600 leukocytes per cubic millimeter, of which 60 per cent were granulocytes. Culture of the fluid showed a luxuriant growth of Type 3 pneumococcus. Blood culture on the same day showed no growth.

Oral administration of sulfathiazole was begun at once; the initial dose was 4 gm., and subsequent doses of 2 gm. were given every 4 hours. Twelve hours later the patient was given 240,000 units of Type 3 antipneumococcus serum intravenously. The improvement was prompt and striking. Within 72 hours of the onset, the spinal fluid was sterile and the temperature reached normal. Chemotherapy was continued for 6 days, a total of 67 gm. of sulfathiazole having been administered.

A summary of the laboratory findings is given in Table I. Convalescence was uneventful except for an attack of lum-

bar pain on the 6th and 7th days of chemotherapy, this, in turn, was followed by a very minor degree of hematuria. Blood chemical determinations at that time showed not only an unusually high free concentration of sulfathiazole, but also a very high level of the conjugated drug. Following the discontinuance of chemotherapy, the pain promptly subsided and the hematuria gradually disappeared.

The pathogenesis of the meningitis in this case is very obscure. Cultures of the pharynx and the

middle therapy alone before serum was administered; combined treatment was instituted because of our uniformly discouraging results in the treatment of pneumococcal meningitis, and because of certain evidence that combined therapy may be indicated generally in Type 3 infections. It may be possible, however, that sulfathiazole diffused through the blood brain barrier to create a con-

*Chemical determinations were made according to the method of Bratton and Marshall² using a sulfathiazole standard

teeth sockets yielded no pneumococci. Roentgenograms of the sinuses and air cells of the skull disclosed no focus of infection. Unfortunately, fluid from the hypopyon was not cultured; a culture from the left eye socket showed no pneumococci. The patient did not have pneumonia. Inasmuch as pneumococci are frequent causative agents of hypopyon, it is not unreasonable to suspect that the meningitis represented a late metastatic lesion from the endophthalmitis.

The employment of two specific agents in the treatment makes it impossible to evaluate either remedy. The patient was improving on sulfona-

centration in the spinal fluid that was equal to those in the blood stream that are frequently associated with bacteriostasis. Moreover, no serum or complement was introduced intrathecally.

SUMMARY

A patient with Type 3 pneumococcal meningitis recovered promptly after treatment with sulfathiazole and antipneumococcus serum.

MEDICAL PROGRESS

ALLERGY: WITH SPECIAL REFERENCE TO DRUG ALLERGY*

FRANCIS M. RACKEMANN, M.D.†

BOSTON

THE current literature dealing with allergy contains an increasing number of reports of queer reactions to queer substances. There are various reasons for this. First, the principles of allergy are being recognized more and more, and the profession and the public are becoming "allergy conscious." Secondly, with the help of allergic principles, many lesions particularly those of the skin, that were formerly passed off as being of minor importance can now be recognized as having a real cause and are reported as such. And thirdly, modern progress, particularly in chemistry, has resulted in the development of a host of new substances encountered in industry, as well as in new forms of medical treatment. More of these new substances are appearing from time to time, and reports of reactions continue to be presented. It is therefore considered worth while to review the present knowledge of the subject.

The fundamental principles are not difficult to understand. The state of hypersensitiveness is acquired by certain people but not by everyone; and this fact raises the question whether the capacity to develop sensitiveness is in itself an unusual and distinct function or whether it is merely an exaggeration of a normal response. The arguments for and against each of these conceptions need not be reviewed here. The fact is that when the person who has the capacity to develop sensitiveness comes into repeated contact with a new foreign substance, he is likely to develop a hypersensitiveness to it. The nature of the foreign substance seems to be relatively unimportant, for as will be seen presently, sensitiveness may be developed to substances of such simple chemical structure as iodine, arsenic and aspirin, or to those of such complexity as egg-white and horse serum at the other end of the scale. The list contains substances of all chemical varieties between the two extremes.

Sensitiveness may arise in various ways and may take on various forms, perhaps in accordance with the mode of exposure. In general, there are two major groups.

The first is *local tissue sensitiveness*, which may develop without evidence of changes in the body as a whole. It is limited to one kind of tissue,

usually the skin, as shown by the fact that in poison-ivy dermatitis the patient can eat the leaves without symptoms, since his mucous membranes are not sensitive. Under the title of "contact dermatitis" a multitude of reports deal with variations in the application of the principles. In other cases, the sensitiveness may be of the mucous membranes rather than of the skin, and one may have lesions of the eye, the mouth (canker sores), the nose (hay fever) or the vagina, all without evidence of sensitiveness in other tissues, as might be shown by positive skin tests or by the presence of skin-sensitizing antibodies in the blood. Whether asthma can be due to a sensitivity localized in the bronchial mucosa is an interesting possibility. In this group of local tissue sensitiveness, skin reactions made by the scratch method are quite negative. Contact dermatitis has been known a long time. The patch test, which reproduces the lesion and confirms the diagnosis, was described by Jadassohn¹ in 1895, which was seven years before Portier and Richet² reported on "anaphylaxis," and eleven years before Von Pirquet³ discussed "allergy." As Sulzberger⁴ remarks, this early work is not often recalled.

The second major group is *general sensitiveness*, that is, a reaction of the whole body. In hay fever, asthma and certain types of dermatitis ("eczema"), the exciting factor, which occurs in dust or foods or drugs, is absorbed into the blood and thus reaches the shock organs in the nose, the bronchi or the skin. The sensitiveness can be transferred locally to normal persons by injecting the skin-sensitizing antibodies of the patient's serum. Skin tests are usually positive.

The relation between hay fever, asthma and flexural eczema of the typical allergic, or more properly called "atopic," varieties, and the less well-defined drug rashes, urticarias, general systemic reactions and blood reactions is not always clear, but at least one can say that they occur in only a small number of persons who are specifically sensitized and that the nature of the symptoms suggests that the process is general and not local. The distinction between reactions that are allergic and those that are toxic depends on whether they occur in only a few patients or quite regularly in all persons exposed to the drug. In other words, the

laboratory, Massachusetts General Hospital.

question is, Does the reaction depend on some change in the particular patient, or is the drug poisonous for all? In a few cases of drug allergy, positive skin tests and skin-sensitizing antibodies have been observed. Whenever the skin is involved, the patch method of testing usually gives positive results; but when the skin is not involved, neither by the scratch nor by the patch

method can the sensitiveness be demonstrated. The relation between the two major groups and their subdivisions is shown in Table 1, and the various points are considered in the following sections.

LOCAL TISSUE SENSITIVENESS

Contact dermatitis is common and may depend on any one of an almost indefinite number of drugs. Sulzberger⁴ gives a list of eight hundred different substances that he has used for patch tests in persons suspected of being sensitive to one or the other. The list is similar to that published in 1939 by Rostenberg and Sulzberger.⁵ On the last page of Sulzberger's paper, one notes, among other items, water colors, Whitfield's ointment, window sprays, oil of wintergreen, witch hazel, xylol, yellow oxide (a dye), zinc sulfate and Zonite, in other words, dyes, medicaments, household chemicals, cosmetics, industrial chemicals and patent medicines—the whole range.

Recent case reports are numerous. Downing's⁶ patient was a window glazier who became sensitive to the orthodichlorobenzene used as a wood preservative. A drop of the solution applied to the arm produced intense erythema and edema in two minutes. In Walter's⁷ patient, hexylresorcinol was applied externally each day for five months. Two years later, the drug was applied again and a severe local dermatitis resulted in vesicular, bullous lesions. Goodman⁸ observed positive patch tests in a patient with severe contact dermatitis who was poisoned by various local anesthetics. He found, however, that only those anesthetics with a para-aminobenzoyl base caused

reactions. No response followed when the amino group was in the meta or ortho position, and other cases have shown that the development of sensitiveness depends not only on the chemical constituents of the substances involved but also on the way in which they are arranged in the compound. Schwartz and Russell⁹ describe an extensive dermatitis in a patient who was found sensitive to the resin used for lining tin cans. So-called "can poisoning" is not uncommon. On the other hand, Henry¹⁰ found that his patient was sensitive to the celery oil in the contents of a can.

Mucous-membrane sensitiveness occasionally occurs, and cases must be looked for. In 1935, Parlato's¹¹ patient was a nun who developed corneal ulcers after exposure to sachets used in the church vestments. She gave a markedly positive skin test to orris powder so that her trouble was of general, rather than local origin. Pfeiffer's¹² patient was sensitive to Pontocaine, so that 2 drops of the 0.5 per cent solution in the eye resulted in the development of massive edema of the eyelids, face and parotid regions that came on in a few hours. Patch tests were positive. Somewhat similar is the case reported by Theodore,¹³ who found his patient sensitive to Larocaine. Parkhurst and Lukens's¹⁴ patient was sensitive to Butyn, and when a 2 per cent solution was dropped in her eye, both eyes became markedly swollen. Patch tests with Butyn and also with a solution of zinc sulfate were positive. In each of these cases, the sensitiveness of the eye was very marked, but one could hardly say that it was limited to this particular mucous membrane.

That vernal conjunctivitis is an atopic illness and not a local process is the conclusion of Lehrfeld and Miller,¹⁵ who studied 120 cases. Many positive skin tests with foods and drugs were found, and the eosinophils were high in both the blood and ocular smears.

In the vagina, local sensitiveness has been recognized. Kesten¹⁶ treated a woman for *Trichomonas vaginitis*, using a powder containing arsenic. In a few minutes, burning and itching developed and became intense, and were followed promptly by a red rash. Whereas the lesion was marked in the mucous membrane, it spread to the skin of the inner aspects of the thighs as well.

A local sensitiveness of the nasal mucosa is a possibility that might account for the fact that certain patients have hay fever but give no positive skin tests to pollens. Occasionally, eye tests made by dropping crude pollen into the conjunctival sac are positive, or further study shows that the skin tests, which were negative in the first years, become positive in later years, suggesting that the disturbance is quite local at first but later spreads

to involve the body as a whole. It may be that certain cases with asthma can be shown to have a similar mechanism dependent on a localized, perhaps "fixed," sensitiveness of the bronchial mucous membrane.

The so-called "fixed drug eruption" was, according to Sulzberger,⁴ described first by Brocq in 1885. Sulzberger recalls that Brocq observed a patient who developed sharply circumscribed, elevated, discolored eruptions whenever a dose of Antipyrine was taken by mouth; these lesions always recurred in the same spots. Here, then, is evidence not only that the skin as a whole may be sensitized, but also that some areas of the skin may be more sensitive than others. Sulzberger reports that in some patients, certain fixed areas will react to one drug whereas others will react to another drug. His patient had a lesion on the hand that flared up regularly when she took a dose of a barbiturate by mouth, and she also had a fixed area on her thigh, which reacted when she took phenolphthalein. The hand did not react to the cathartic, nor did the thigh react to the sedative. Sensitiveness was not only localized—it was highly specific. Meredith¹⁷ observed a thirty-nine-year-old woman who had two round inflamed areas on the neck and one on the thigh. In a series of experiments, it could be shown that any barbiturate, such as Allonal, Sedormid, Dial or Sodium Amytal,—the last being the worst,—could cause a flare-up in these particular areas. The literature has been reviewed by Wise and Sulzberger,¹⁸ and more recently by Abramowitz and Noun.¹⁹

GENERAL SENSITIVENESS

General sensitiveness is somewhat easier to understand, since the vast number of patients with so-called "atopy," that is, hay fever, asthma and atopic eczema, provide typical illustrations. The capacity to develop this type of sensitivity is inherited: skin tests are positive, and skin-sensitizing antibodies can be demonstrated in the blood. It is important to keep the group in mind as the more general effects of drug allergy are considered briefly from here on.

Systemic reactions from drugs are not unknown. In 1933, Short and Bauer²⁰ reviewed the literature on cinchophen hypersensitiveness. They found 41 cases and added 4 of their own. All were made sick by the drug, and 3 patients developed urticaria. In 1937, Boros²¹ described a patient who developed jaundice and later ascites after taking cinchophen. In 1938, Sugg²² collected 32 cases of cinchophen poisoning, 22 of which had evidence of liver damage; 10 of these patients died; 10

others had extensive skin lesions, and 2 died. The drug was toxic.

Avertin caused death in 7 cases reported by Beecher,²³ who discusses the differences between allergic reactions and toxic effects, emphasizing that severe reactions occur only in a few people and thus point to a change in make-up. More recently, Dolan²⁴ and Crane²⁵ have described the occurrence of sudden death following the intravenous administration of an iodine-containing dye, called Diodrast, used in urography. In hundreds of other cases, it has caused no trouble.

Acute asthma can be caused by drugs. The asthmatic patients sensitive to acetylsalicylic acid (Aspirin) form almost a special group, because they are always difficult to deal with. Objective tests with the drug are unsatisfactory; the skin test is negative. Several reports of such cases were summarized in 1937 by Prickman and Buchstein.²⁶ In the same group, but less common, are other cases. Martinaud²⁷ observed a fatal attack of asthma that came on when the nasal mucosa was washed with a solution of Butyn. An injection of quinidine caused angioneurotic edema of the lips and larynx, and the next dose caused urticaria, shock and death, in a patient reported by Breu and Zollner,²⁸ the only case of quinidine poisoning in the literature. Another report is that of the McCastors,²⁹ who in five days after the first dose injected sodium morrhuate into the varicose veins of a thirty-year-old man. Suddenly he turned pale, then became cyanotic and collapsed, but with artificial respiration, epinephrine and Coramine he revived slowly. In another case, a similar though less violent reaction followed injection of sodium morrhuate into a hydrocele. The authors emphasize, however, that these were the only reactions in a series of twenty-five hundred injections. Two industrial chemicals are reported as a cause of asthma. Card's³⁰ patient was sensitive to the chromium used in a plating factory, and Kern's³¹ patient was sensitive to phthalic anhydride, a dye made from naphthalene.

Dermatitis medicamentosa is an old term that appears in many textbooks, and under it the generalized rashes due to bromides, iodides and arsenic salts are often described. In the literature up to 1937 Seymour³² found reports of 14 cases in which the local application of iodine had caused severe generalized eruptions; 7 of these were fatal, and he added another case. In 1937, Beijerinck³³ added a sixteenth, and also fatal, case of so-called "ioderma" with extensive generalized dermatitis caused by the injection of 1 gm. of potassium iodide daily for fourteen days.

Fanburg³⁴ has described a patient with exfolia-

tive dermatitis due to naphthalene on clothes stored in a moth proof closet.

In 1932, Bullen, Francis and Parker³⁵ reported 2 cases in which the ingestion of ephedrine caused the development of a generalized dermatitis followed by desquamation, and the next year Scheer and Keil³⁶ reported on scarlatiniform eruptions after cocaine. Gelfand³⁷ observed a woman who had marked generalized dermatitis from the application of a hair tonic and dandruff remover, and Settle³⁸ described the case of a young man whose extensive skin lesions were due to quinine. Baker and Brunsing³⁹ observed the sulfocyanates as a cause of dermatitis, and Brandt⁴⁰ discovered that the recurrent eczema in a forty five year-old woman came and went as her digitalis was prescribed or omitted.

The reactions to arsphenamine are of more practical importance. They occur oftener during the first course of treatment, and thus may depend more on the toxicity of the drug than on the allergy of the patient. Dermatitis is a contraindication to further treatment—at least with the particular preparation that caused it. Schoch, Alexander and Long⁴¹ have recently collected a series of cases and have shown that in most of them, treatment could be tolerated without further trouble. They suggest that the sensitiveness is directed not to the arsenic itself but to the particular chemical complex of which it is but a part. The Herxheimer reaction is said to be due to the flare up of the syphilitic lesion, like the so-called "provocative Wassermann reactions" in vogue some years ago. It may also be a form of local allergy. Nitritoid crises are immediate reactions with flushing of the skin, palpitation, collapse and sometimes asthma from edema of the bronchial mucosa, which come on suddenly, immediately after or often during the actual injection of arsenicals. Since these reactions occur in only a few patients, one may assume that allergy plays a part. They provide another illustration of the acute systemic responses described above.

Comparative studies of similar phenomena are as useful in allergy as in chemistry. Professor Sanger, who used to lecture in elementary chemistry at Harvard College, demonstrated that the physical and chemical properties of the elements varied in a rather orderly fashion in accordance with their atomic weights, and he predicted correctly that several blanks in his large periodic table would be filled in. And so it is with drug allergy. The sulfanilamide drugs have complex formulas, they produce severe general reactions occasionally, and now that they are being used more and more for purely local treatment, local contact dermatitis can be almost expected; so far,

however, I have not seen them. Toxic reactions, on the other hand, have been reported frequently, especially after later doses, when the drug had been repeated in a new and separate course of treatment, and deaths have occurred. Long and Bliss⁴² reviewed the literature up to 1939. They did not mention local reactions, but two reports (Tedder,⁴³ Hallam⁴⁴) lay stress on photosensitivity, which gave rise to extensive skin lesions in patients who had taken sulfanilamide or sulfapyridine and then were exposed to the sun or to an ultraviolet lamp. In these cases, the reaction was of a special type and consequently more toxic than allergic, even if observed in only a few of many patients.

Urticaria may be due to drug allergy. Indeed, urticaria and erythema multiforme are often part of the severe systemic reactions described above. Urticaria may also precede and be a part of generalized skin reactions. Reports of pure urticaria from drugs alone are not common. One difficulty is that whereas salicylates, barbiturates, morphine, iodine and phenolphthalein have been suspected as the cause of urticaria,—since rashes appeared when the drugs were given and cleared when they were withdrawn,—other factors are always hard to control. There is no doubt, however, that drugs of any sort are quite capable of causing hives.

Blood dyscrasias comprise another chain of symptoms that depend on a generalized sensitiveness of the body. Primary granulocytopenia (agranulocytosis) was first described in 1922 by Schultz,⁴⁵ but was first recognized as being due to drug poisoning by Squier and Madison⁴⁶ in 1933. In 1935, Hunter⁴⁷ reviewed the literature completely and pointed out that in most cases there was a story of previous use of the drug, and an interval before the second use, which caused the severe attack. The triad of first dose, interval and second dose may be compared with the anaphylactic experiment. In 1936, Dameshek and Colmes⁴⁸ were able to combine amidopyrine with serum to make a drug-protein linkage and thus to substantiate the role of allergy as the background for agranulocytosis. Between 1934 and 1938, cases sensitive to amidopyrine were reported with some frequency. Since then, the reports have been fewer, evidently because the dangers have been recognized and precautions in the way of careful following of the blood picture have been instituted.

Purpura from drugs is not uncommon, and the literature has been reviewed by Falconer and Schumacher⁴⁹ and by McGovern and Wright.⁵⁰ Sedorimid (allylisopropyl acetylcarbimide) seems to be a common cause, for it is reported several times

in recent literature. Purpura has followed the use of gold and arsenic compounds, as described by Hudson,⁵¹ and was caused by quinine in the case reported by Beiglböck.⁵²

Aplastic anemia may likewise be due to an allergic reaction caused by drugs. It has been found to follow the use of neoarsphenamine. Kadin⁵³ reviews the literature and adds 3 cases of his own.

It is very hard to determine why in certain people allergy causes a lesion of the bone marrow affecting the white cells, whereas in others it results in a disturbance of the blood platelets. One can speculate on the variations in the sensitivity of certain parts of the blood-forming mechanism and compare them with the different forms of contact dermatitis,—a sensitiveness of the skin in general, and the fixed drug eruption, in which only a portion of the skin is affected,—but there is no real knowledge of the subject.

Certain *miscellaneous diseases* deserve mention. Headache (migraine), joint pains and dysmenorrhea have been described as due to specific foods, but there is no report that incriminates drugs as a definite proved cause of these common symptoms. The possibility is included here merely as a suggestion and with the expectation that this blank also will be filled in. Sensitivity to hormones—insulin and liver and pituitary extract—occurs in occasional cases and rests quite firmly on a basis of allergy. Guinea pigs have been sensitized to crystalline insulin by Berstein and his associates.⁵⁴ Certain patients may be sensitive to the insulin alone, just as other patients appear to be sensitive to the animal from which the insulin was obtained and are relieved of trouble when the type of insulin is changed as from beef to hog. Similarly, in pituitary extracts, Simon and Ryder⁵⁵ found that sensitiveness depended on an organ-specific rather than a species-specific quality of the material.

DISCUSSION

The principal object of this brief review has been to call attention to the subject of drug allergy. It is not a very common disease, but it occurs often enough to be considered whenever a queer reaction occurs and results in a clinical picture that does not quite fit a recognized disease. One should think of the possibility that such a reaction depends on a hypersensitiveness to a queer substance: perhaps a drug, or perhaps some special chemical substance associated with home or occupation. Also, it is evident that drugs may be the principal cause of such definite conditions as asthma, urticaria, purpura, and agranulocytosis.

Another object of this review has been to call

attention to the multiplicity and the variety of reactions that drugs can produce, and then to arrange them in some sort of order so as to show the relation of one to the other and the relation between them and the better known clinical manifestations of allergy, like hay fever and asthma. It is emphasized that a hypersensitiveness to drugs may take on different forms and may result in a variety of different syndromes.

Finally, it appears that a study of the reactions to drugs is of considerable interest in its bearing on the reactions to other substances, especially the proteins and the pollens. The study of contact dermatitis is of particular importance because it suggests that sensitiveness may be localized to certain tissues or may at least be much more marked in one tissue than in another. This idea is similar to Coca's conception of a "shock organ," but the present emphasis is on the mechanism of the reaction, which is localized and results from direct local contact and consequently differs from the mechanism of other reactions, which, in turn, are more generalized and develop from contact with the specific substances through the blood stream.

This conception of local tissue hypersensitiveness needs much more study. The cases of contact dermatitis support the idea quite well, but when one tries to apply the same conception to the study of the mucous membrane, good support is hard to find. On the other hand, it is true that among hay-fever patients, there are some whose symptoms are typical, whose tests of the skin are quite negative, but who do react when pollen in crude dry form is dropped into the eye. Here is real evidence of a purely local process. The understanding of the problem of contact dermatitis becomes easier when that of hay fever is understood, and vice versa. Incidentally, is not ragweed hay fever in the nose of one patient and ragweed dermatitis of the face and wrists of another evidence of the varying predisposition of different local tissues? In this reaction, however, the chemical difference between the oleo resin, which can penetrate the skin, and the protein, which is soluble in the nasal secretion, may be significant. One's outlook must always be as broad as possible, so that one set of circumstances can be compared with the other, with profit to both.

Meanwhile, nothing has been said concerning the treatment of drug allergy. It should almost go without saying that treatment is synonymous with the diagnosis, which depends on two factors: first, thinking of the possibility, and secondly, studying the history. Just as in the study of hay fever and asthma, the dates and the circum-

stances of the attack give the clues by which the good detective can find the answer. Skin tests, especially by the patch method, are useful, but are positive only when the skin itself is involved. Drug allergy gives further evidence that clinical sensitiveness can exist even when the skin tests are negative

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27161

PRESENTATION OF CASE

First Admission. A fifty-three-year-old housewife entered the hospital complaining of dysmenorrhea.

The patient had been well until seven years previously, when her normal periods became irregular. Each year for the next three she suffered four attacks of transitory but severe lower abdominal pain, which occurred on the third day of what appeared to be a normal period. The pain was relieved in a short time by the onset of rather pronounced vaginal bleeding, which lasted several days. Four years before admission the menstrual periods became more regular, and the patient noticed hot flashes of decreasing severity. Two years later another attack of abdominal pain occurred, which was relieved by the onset of bleeding and the passage of "tissue"; no further attacks of this nature had appeared, but menstruation became more irregular and scant and generalized weakness came to the fore. A year and a half before admission the patient had a normal menstrual period. Six months prior to entry marked the onset of a brownish, odorless vaginal discharge, with occasional bright-red streaking, accompanied by a dragging sensation in the pelvis, and low backache; these symptoms persisted and were present at the time of admission. In addition the patient noticed that her hair was becoming dry and sparse, and that frequent headaches occurred that were more noticeable in the morning. Three months before admission she suffered an attack of upper abdominal pain, which lasted four days and was accompanied by nausea, loose yellow stools and "darkening" of the skin. Her physician could not detect jaundice, and there was no visible change in the urine. A bland fat-free diet was instituted, and the attack was not repeated; the patient had never liked fatty food and was troubled by "gas on the stomach." Furthermore, she stated that she had shaved once a day for "years," had lost weight in the past few months, and had noted stinging pain in the fingers and toes for an undisclosed period.

The patient had five children who were well; she had had three miscarriages. Seventeen years

before entry, a uterine suspension had been performed at another hospital.

On examination the patient was well developed, somewhat obese, and in no acute distress. The hair of the scalp was dry and receding, and there was facial hirsutism; the skin appeared atrophic. The heart, lungs and abdomen were negative apart from a mid-line surgical scar between the umbilicus and symphysis pubis; the blood pressure was 220 systolic, 100 diastolic. Pelvic examination revealed an enlarged clitoris with a relaxed perineum. The cervix was freely movable, and the fundus was normal in shape, but slightly enlarged. The vaults and adnexa were clear. Examination of the nervous system and eyes was negative except for a mild vascular sclerosis of the retinal vessels.

The temperature, pulse and respirations were normal.

Examination of the urine was negative. The blood showed a red-cell count of 4,940,000 with a hemoglobin of 94 per cent, and a white-cell count of 8400. The nonprotein nitrogen of the blood serum was 19 mg. per 100 cc. A sugar-tolerance test using 50 gm. of glucose showed a fasting blood sugar of 90 mg. per 100 cc., in half an hour 143 mg., in one and a half hours 204 mg. and in three hours 171 mg. The insulin-glucose-tolerance test showed slight insulin resistance. A blood Hinton reaction was negative, and a phenolsulfonephthalein test was normal. The cervical culture was negative for beta-hemolytic streptococci. Assays for 17-ketosteroids on two occasions gave values of 3.9 and 5.5 mg. in twenty-four-hour urine specimens.

X-ray studies of the chest were negative. A Graham test and intravenous pyelogram showed normal gall bladder and kidneys. Air injection revealed no enlargement of the adrenal glands.

An electrocardiographic recording showed a normal rhythm with a rate of 80 and a PR interval of 0.15 second. There was slight right-axis deviation and slight inversion of T₃.

On the third hospital day, a pelvic examination under ether and a dilatation and curettage were performed. The cervix had apparently been amputated at a previous operation, and it was found that firm adhesions had formed across its mouth which required division before the os could be found. The fundus was of average size, and 11 cm. in depth; the vaults were clear, and no masses were palpable in the flanks. Curettage yielded three fragments of endometrial tissue resembling endometrial polyps; elsewhere the interior of the uterus was smooth. Pathological examination of these fragments revealed chronically inflamed cervix

polyps, no endometrial tissue was identified. The patient was discharged three weeks after admission.

Second Admission (six months later) The patient remained well until three months after discharge, when slight vaginal bleeding reappeared. It was bright red, sometimes had a slightly unpleasant odor, and occurred at intervals of two or three weeks, lasting two to seven days. At this same time she suffered from transient attacks of nonradiating lower abdominal aching and soreness that coincided with the bleeding or was independent of it. One month before admission she visited the Out Patient Department, and the examiner believed a mass to be present in the left vaginal vault. At the time of admission, the patient stated that her head felt full and thick and that her memory was poor.

Physical examination was as before, with the following additional and contributory findings. The skin was oily, with a generalized mild acne. The blood pressure was 180 systolic, 115 diastolic. There were tenderness and slight spasm in both lower quadrants of the abdomen. The vagina contained blood, but the degree of tenderness in both vaults prevented an adequate examination.

On the third hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR MAURICE FREMONT SMITH. It may be well to start off by pointing out that this woman was perfectly normal up to the time of the menopause. She had normal periods and had had five children. That is satisfactory evidence that she was, from the endocrinologic point of view, normal. She began having irregular periods at the age of forty-six, which is a normal time for the onset of the menopause. She had attacks of lower abdominal pain occurring on the third day of bleeding and relieved after the bleeding got underway. The chief complaint simulates dysmenorrhea. Of course, unless one uses the term "dysmenorrhea" to include all painful bleeding, this is not dysmenorrhea. Dysmenorrhea characteristically occurs early in life, rarely when a person has had a number of children. In fact, to have children is one of the best treatments of dysmenorrhea. It does not start at this age. This was painful bleeding, and should be put in the group with ectopic pregnancy, miscarriage, endometriosis and pelvic inflammatory disease, all of which produce pain with bleeding but are not what we term "dysmenorrhea." The cause of this painful bleeding is, I think, adequately explained by the later findings. The cervix having been amputated, scar tissue had grown over the end, and

when she menstruated, she bled into the uterus, the uterus tried to empty itself and could not; the patient had the same sort of pain that occurs with threatened miscarriage. When blood passed, the pain was relieved.

Four years before admission the periods became more irregular, and the patient had hot flashes, which, again, are perfectly normal menopausal symptoms. The hot flashes show that the pituitary gland was working, putting out follicular stimulating hormone, and an assay would have shown that follicle stimulating hormone was present. The hot flashes grew less frequent. I think that was probably normal, as she adjusted herself to the increased follicle stimulating hormone.

Two years before admission the patient complained of generalized weakness. That may be an important symptom to remember. At fifty-one she had a so called "normal period." In other words, she had bleeding without pain and may have had what might again be normal—a period of anovulatory bleeding coming once after the beginning of the menopause. Six months later she had discharge, with bright red streaking. Discharge after the menopause naturally brings up the question of carcinoma of the uterus. I think we can quickly dispose of that, however, because a thorough ether examination and curettage showed an atrophic endometrium, a few cervical polyps but certainly no cancer of the fundus, which would be the type of cancer expected at this age. The patient also had headaches, which we must remember, and she had sparse hair, to which I am unable to attach any significance. She had this queer attack of upper abdominal pain and yellow stools, with no apparent jaundice, and later she showed a diabetic sugar curve. She might have had an attack of mild, acute pancreatitis. She apparently did not have what one would first think of,—gallstones,—because she had a negative cholecystogram. Of course one can have gallstones in the presence of a negative cholecystogram, but she had no jaundice and no further attacks, and we either have to leave it unexplained or consider that she had an attack of pancreatitis.

The patient had shaved once a day for years. It would be helpful to know whether the hirsutism came on at a specific time in adult life or whether it fell into the very much larger group of hirsutism that has no endocrinologic basis. In 90 per cent of cases, hirsutism comes on at about the age of puberty and is due to disease of the hair follicles, which respond excessively to the normal steroids of the body. The end organ is at fault, not the endocrine glands. On the other hand, hirsutism can be evidence of a masculinizing process, but I think the fact that she shaved for years prob-

ably throws it into the larger group of congenital hirsutism.

The stinging pain in the toes and fingers, I cannot comment on.

As to the physical examination, there are some very important points. The patient was obese; the hair of the skull was receding; she had facial hirsutism. She had an atrophic skin, a high blood pressure and evidence by electrocardiogram of coronary arteriosclerosis. She had an enlarged clitoris. There was nothing abnormal in the vaults. These symptoms suggest Cushing's syndrome. We should like to know whether she had any osteoporosis. We have no x-ray films of the bones, but in Cushing's syndrome obesity is present, in addition to striae,—which are not mentioned here,—hypertension, arteriosclerosis, and a diabetic type of sugar curve.

Let us for a moment talk about the sugar curve. There was a glucose-tolerance curve of the diabetic type, and then we are told that there was slight insulin resistance. In ordinary diabetes we have, of course, a diabetic curve. If insulin is given, the curve is lowered. If one gives an insulin-glucose-tolerance test in which the insulin and glucose are balanced, one gets a rather flat curve. The sugar does not go up very high. In such a case the insulin is effective. In diabetes the reason that the sugar is high is that there is lack of insulin. We have been taught that insulin increases the tissue utilization of sugar. Soskin* says that in diabetes the tissue use of sugar is perfectly normal and that insulin acts by slowing down the production of sugar from the liver (which is constantly putting out sugar into the blood), but wherever insulin acts in diabetes, the insulin is effective on the blood sugar. There are two other conditions, however, in which insulin is not effective. With an overactivity of the eosinophilic cells of the pituitary gland, there is an overproduction of the hormone that inhibits insulin—the glycotrophic hormone of the pituitary. If a glucose-tolerance test is performed and insulin is given at the same time, the insulin is inhibited by the pituitary hormone and is not active. Therefore, the curve is much as it was originally—very little influenced by the insulin. The curve approaches the diabetic curve, and the insulin is not effective. Another condition in which insulin does not change the diabetic curve is hyperactivity of the adrenocortical cells, which is thought to be the physiologic explanation of Cushing's disease. In such cases the adrenocortical cells produce a hormone that breaks down protein in the body into sugar very rapidly. There is thus an overproduction of sugar,

and the insulin that is added—there being enough insulin in the body anyway—does not affect the glucose-tolerance curve.

Going back to Cushing's disease for a moment, Cushing's disease is due to an overactivity of the cortical cells of the adrenal glands. It was originally described as a basophilic tumor of the pituitary gland, the latter stimulating the adrenal glands to the production of the adrenotropic hormone, which, as previously mentioned, breaks down protein into sugar. On the other hand, some cases of Cushing's disease show no tumor of the pituitary gland. Some of them simply show hyperplasia of the adrenal glands, and in others Cushing's syndrome may occur with cancer of the adrenal glands. In all these cases, there are questionable compensatory changes in the pituitary gland. Apparently Cushing's syndrome can occur either as a primary condition in the adrenal glands, primary overactivity or as a secondary overactivity caused by a basophilic tumor of the pituitary gland. As I have said, many of these physical signs are consistent with Cushing's disease, as is the glucose-tolerance curve and the response to insulin. On the other hand, there are three things that do not fit in with Cushing's disease: The patient was still bleeding, and in Cushing's disease amenorrhea is one of the outstanding symptoms; she had an enlarged clitoris, which is not found in Cushing's disease—it does produce hirsutism without virilism; and she had low 17-ketosteroids,—about 5 mg.,—almost all cases of Cushing's disease (I think Dr. Albright will agree) having high ketosteroids, and all cases of cancer of the adrenal gland having tremendously high values, even up to 100 mg. We have these three things to explain if we say that this patient had Cushing's disease. How can we explain the enlarged clitoris? If we accept that finding, we have to explain it by some masculinizing type of tumor—adenoma of the androgenic cells of the adrenal gland or tumor of the ovary of the masculinizing type. On the second admission, the patient had pain in the pelvis, with tenderness after bleeding and with great tenderness on examination. Might there be an ovarian tumor of some type? Against this is the fact that she had been examined under ether and nothing had been felt; but one of the men in the Out Patient Department thought that he did feel a mass. If we consider the ovarian tumors that cause bleeding after the menopause—and with bleeding after the menopause ovarian tumors must always be considered—and if we also consider ovarian tumors that have endocrine activity, we have to consider three: granulosa-cell tumors, thecal-cell tumors and arrhenoblastomas. The first two are feminizing tumors and cause bleeding by

*Soskin, S. The blood sugar: its origin, regulation and utilization. *Physiol. Rev.* 21:140-193, 1941.

the overproduction of estrin, which in turn produces hyperplasia of the endometrium. At operation the endometrium was atrophic. The arrhenoblastoma is a virilizing tumor and would account for the large clitoris, but would not account for the weakness, because patients with this type of tumor are strong. It would not account for bleeding, because the virilizing tumor characteristically stops bleeding. Dr. Albright has seen one case of arrhenoblastoma in which periods went on but ovulation ceased. Arrhenoblastoma would not explain the changes in the sugar metabolism. We have on examination no evidence for a Cushing's tumor of the adrenal gland, nor have we any evidence for a tumor in the ovary. We cannot explain the bleeding and the large clitoris satisfactorily from any one point of view. There is one other possibility. This woman did have headaches. We are not told anything about the possibility of acromegaly. Acromegaly might explain the picture. We could have a diabetic curve due to insulin resistance. The ketosteroids would not be raised. We are not told about the visual fields; we are told only that the eyes were normal. We are not told about the phosphorus, which may be increased in acromegaly, nor are we told about the facies and teeth. I think that we must consider acromegaly as a possibility.

The only way that I can put this case together is as follows: It is possible that this woman was bleeding from an atrophic uterus, that she forced blood out of the tubes into the pelvis, causing a localized aseptic peritonitis, which might explain the pelvic situation. I do not see how we can explain the whole picture on the basis of ovarian tumor. The enlarged clitoris I shall have to put down as unexplained,—that she was a big woman and had a big clitoris, or the examiner was not conversant with the various sizes of the clitoris. I believe that this case fits best into the Cushing's disease group, and I should like to ask Dr. Albright if the ketosteroids are always high in that disease. If that is so, and if the ketosteroids were low normal here, I should be forced back to the hypothesis that the patient had an eosinophilic tumor of the pituitary gland.

DR. FULLER ALBRIGHT: I think we can give Dr. Fremont-Smith more information. I should like to say that the skin was not atrophic. What was the follicle-stimulating hormone test in the urine before operation?

DR. TRACY B. MALLORY: It was not done until two days after operation, when it was negative.

DR. FREMONT-SMITH: That would mean that the basophilic cells were not active, as they should be after the menopause. That makes one believe there was something interfering with the basophilic

cells, such as tumor of the eosinophilic cells. Is there any more information that I could have?

DR. ALBRIGHT: You have not commented on the acne.

DR. FREMONT-SMITH: I wish you would comment on that.

DR. ALBRIGHT: I think Dr. Fremont-Smith has given an excellent discussion. He did not come out with the right answer any more than those who saw the patient before the operation. To one like myself, who saw her only after the diagnosis was made, it was easy to see that the findings fitted in with the correct diagnosis. The follicle-stimulating-hormone test two days after operation was negative and presumably was negative before operation. This test should be positive after the menopause unless some factor is present that inhibits its production. One of the hormones that does just this is testosterone. The fact that this test was negative, therefore, would make one go back to the possibility of an arrhenoblastoma, which produces either testosterone or, what is more likely, a testosteronelike steroid. Furthermore, testosterone does produce acne. The patient had hot flashes at one time, which is strong evidence, in my opinion, that at that time she had an excess production of follicle-stimulating hormone. It would be my interpretation that the arrhenoblastoma developed subsequent to the time when the patient was having hot flashes. It is of interest that the follicle-stimulating-hormone test, done some time after the arrhenoblastoma was removed, was strongly positive, as was to be expected.

DR. FREMONT-SMITH: How about the sugar curve?

DR. ALBRIGHT: I cannot answer that. It is of interest that the glucose-tolerance test done some time after operation was perfectly normal. I do not know whether this indicates that the arrhenoblastoma had an effect on sugar metabolism, or whether the patient was not properly prepared for the first test. I am inclined to the latter interpretation. Incidentally, the glucose-insulin-tolerance tests did not show insulin resistance, as stated above.

DR. FREMONT-SMITH: How about the bleeding?

DR. ALBRIGHT: I think you explained it—an atrophic uterus.

DR. FREMONT-SMITH: In fairness I think I should say that I thought they operated on the uterus to get rid of the bleeding.

DR. MALLORY: The only preoperative diagnosis that they committed themselves to was postmenopausal bleeding.

DR. FREMONT-SMITH: How about the ketosteroids?

DR. ALBRIGHT: In our one other case of arrhenoblastoma in which the 17-ketosteroids were measured they were found to be normal.

DR. MALLORY: But should they not be high?

DR. ALBRIGHT: They should be if the arrhenoblastoma produces testosterone. There are several steroids similar to testosterone that are masculinizing but are not 17-ketosteroids.

DR. FREMONT-SMITH: Are the ketosteroids always high in Cushing's disease?

DR. ALBRIGHT: No. However, if you take into account that most patients with Cushing's syndrome are very debilitated, a condition that in itself leads to low 17-ketosteroid excretion, I think it is fair to say that the 17-ketosteroids are either high or relatively high.

CLINICAL DIAGNOSIS

Postmenopausal bleeding.

DR. FREMONT-SMITH'S DIAGNOSIS

Cushing's syndrome.

ANATOMICAL DIAGNOSIS

Adenoma testiculare of ovary.

PATHOLOGICAL DISCUSSION

DR. MALLORY: At operation the old abdominal scar was opened up and an exploration performed. The surgeon palpated both adrenal glands and reported that they felt larger than normal, but could find no evidence of tumor in either. I think it is reasonable to question even that first statement, because my experience is that the surgeon always thinks the adrenals are larger than normal if he palpates them. One naturally visualizes the adrenal glands as they are seen at autopsy, when they contain no blood. The adrenal gland is distinctly larger in life than it is at autopsy.

The pelvis was more carefully explored, and a sharply localized tumor was found in the right ovary, which measured 3 by 2 by 2 cm., and was yellowish in color. At that point they became convinced that they were dealing with an arrhenoblastoma. Since, however, the most distressing symptom had been the uterine bleeding, they considered it wise to do a hysterectomy and get rid of the focus of bleeding, as well as to remove the ovarian tumor. In our laboratory when the tumor was examined it turned out to be the more highly differentiated form of masculinizing tumor known as the "adenoma testiculare of Pick" rather than the so-called "arrhenoblastoma." The older literature would lead one to believe that the adenoma testiculare is not a functioning tumor, but this is the second we have

had in this hospital in which there was evidence of a masculinizing action.

CASE 27162

PRESENTATION OF CASE

First Admission. A sixty-five-year-old wool cutter entered the hospital complaining of burning and frequency of urination.

Three months before admission the patient cut his left leg. The lesion was slight and he continued working, but it did not heal, discharged a dirty purulent material, and gradually progressed to a deep ulcer. Pain, redness and swelling developed in the leg to a point necessitating hospitalization.

One week before admission, the patient awoke with a gripping sensation in the right chest, accompanied by a cough and a small amount of blood-streaked sputum. The sputum lasted for one day, but the chest pain continued for three days.

Four years before admission, the patient had been refused life insurance because of high blood pressure. Since that time he had noticed a progressive decrease in his exercise tolerance, so that at the time of admission he was unable to climb a flight of stairs without dyspnea. Of recent weeks swelling had appeared in the feet and ankles of both legs.

He complained also of occasional nocturia for an unstated period. He had had scarlet fever, and twenty-five years before admission "bronchial asthma" for six months. Usually he drank one or two glasses of beer each day and up until two years before admission anywhere from a half pint to two pints of whiskey a week. The patient's father had died of carcinoma of the stomach.

On examination the patient was well developed, well nourished and very drowsy. The tongue was dry, the pharynx injected and covered with a purulent exudate. The lungs were clear, the heart slightly enlarged to the left, but otherwise normal; the blood pressure was 118 systolic, 78 diastolic. The peripheral arteries were soft and pliable. The abdomen was protuberant, and the smooth, non-tender liver was palpable 3 fingerbreadths below the right costal margin. Slight pitting edema of the sacrum was present. The prostate was slightly enlarged, but not of abnormal consistence. The right leg was reddened from the toes to the knee, with a sharp, but irregular line of demarcation at the normal skin border. The upper portion was hemorrhagic and did not blanch on pressure. A 4.5-cm. ulcer with a dirty base and surrounded by small pustules was present over the lower tibia.

The entire lower leg was tender and indurated without fluctuation, and the left thigh was pink and edematous, especially on its medial aspect. There was pitting edema of both lower legs, and the right lower leg showed areas of hemorrhagic discoloration. Pulsation could not be felt in either dorsalis pedis or posterior tibial arteries, but was present in the popliteals and femorals.

The temperature was 100.2°F, the pulse 82 and the respirations 23.

The urine gave a green and occasionally an orange sugar reaction. The blood showed a red-cell count of 4,650,000 with a hemoglobin of 85 per cent, and a white-cell count of 15,000 with 86 per cent polymorphonuclears. The fasting blood sugar was 127 mg, the nonprotein nitrogen 27 mg and the protein 5.4 gm. per 100 cc. The prothrombin time was 24 seconds (normal 19), a hematocrit reading 44 per cent, the vitamin C 0.5 mg per 100 cc.

An x-ray film of the legs showed a marked irregularity of the soft tissue about the left lower leg, with a defect anteriorly and posteriorly. There was very slight calcification along the anterior aspect of the tibia. No periosteal new bone formation was visible.

The patient was given sulfanilamide, intravenous fluids and digitalis, the blood sugar being controlled by diet and insulin. Cultures from the ulcers yielded *Bacillus subtilis*, *Proteus vulgaris* and *Staphylococcus aureus*. Two days after admission, a slight icteric tint was noted in the scleras and the serum van den Bergh at this time was 6.5 mg. per 100 cc, biphasic; sulfanilamide therapy was discontinued and a high-vitamin, high-carbohydrate and low fat diet instituted. The patient's legs improved very favorably, and the edema subsided, but a week after admission a deep ulceration with purple margins and dirty base developed in the left calf and two days later was found to communicate with a collection of pus between the muscle planes; this was incised and drained under local anesthesia. Subsequently a carbuncle of the left buttock appeared, and excision was necessary. Under treatment the patient slowly improved, and the ulcers healed with the aid of pinch grafts. The diet was readjusted to combat the hyperglycemia, and the patient was discharged eight weeks after admission, at which time the serum van den Bergh was 2.0 mg. per 100 cc, biphasic, and a bromsulphalein test showed 10 per cent retention of the dye. The last urine specimen, recorded three weeks before discharge, was negative, and 28 previous specimens had contained no sugar.

Final Admission (seventeen days later). Shortly after leaving the hospital, the patient began to

have urinary difficulties in the form of hesitancy, frequency with large quantities voided, and a slow, weak stream. In addition, there was burning, and nocturia thrice a night. He denied hematuria, chills, fever, nausea or vomiting. For the previous week he had suffered from a nonradiating, dull, aching pain in the left flank and costovertebral angle. Two days before admission, he was unable to void and was catheterized by his physician.

On examination the patient was drowsy and in moderate distress. The heart and lungs were essentially normal, the blood pressure 130 systolic, 85 diastolic. There was exquisite tenderness, bulging and spasm in the left costovertebral angle; the liver was palpable three fingerbreadths below the costal margin. The prostate was greatly enlarged, smooth, symmetrical and firm. Peripheral edema was not present.

The temperature was 101.5°F, the pulse 72, and the respirations 20.

The urine showed a +++ test for albumin and was loaded with white blood cells and bacteria; a culture yielded abundant colonies of nonhemolytic streptococci and *Staph. albus*. The blood showed a red cell count of 3,400,000 with a hemoglobin of 60 per cent, and a white-cell count of 38,900 with 96 per cent polymorphonuclears. The fasting blood sugar was 142 mg, the nonprotein nitrogen of the serum 45 mg, the protein 5.8 gm. per 100 cc, the chlorides being 835 milliequiv and the carbon dioxide combining power 26.6 milliequiv per liter. A phenolsulfonephthalein test showed 7 per cent excretion of the dye in two hours.

An intravenous pyelogram was unsatisfactory, owing to marked respiratory motion on all films. The colon was markedly distended with air and appeared slightly dilated down to the sigmoid; the rectum was not dilated. No filling of the kidneys was visible on any of the films, and no dye was seen in the bladder at the end of forty-five minutes. An electrocardiographic recording showed a normal rhythm at 100 and a PR interval of 0.17 second. There was marked left axis deviation, S₂ was deep, ST segments were slightly depressed in Lead 1 and elevated in Lead 3 and T₁ was biphasic.

Slow decompression of the bladder was carried out, and chemotherapy and intravenous fluids, guarded by insulin, given. On the third hospital day the prostate was found to be tender and fluctuant, so that a perineal drainage of the abscess was performed; a culture of its purulent contents yielded *Staph. aureus*. Throughout hospitalization the patient was stuporous and toxic, respiration became labored, the temperature rose to 102°F and the pulse to 110. One week after admission

the nonprotein nitrogen was 90 mg. per 100 cc., the chlorides 91.7 milliequiv. and the carbon dioxide combining power 21.8 milliequiv. per liter. A flat abdominal film showed apparent thickening in the soft tissues in the region of the right psoas muscle, and the left psoas muscle was but faintly visualized. An x-ray film of the chest taken with a portable machine showed poor aeration of both lower lung fields, more marked on the left side, where there was definite evidence of consolidation consistent with pneumonia. Two days later cystoscopic examination was performed. The bladder mucosa was pale, lackluster and edematous, and the ureteral orifices were edematous. Catheters were passed to both kidneys, and this was followed by hydronephrotic drips from both. The culture from the left kidney yielded *Staph. aureus*, that from the right, a moderate growth of nonhemolytic streptococci. Finally the patient became comatose and dyspneic, edema developed to the scrotum, and the nonprotein nitrogen rose to 100 mg. per 100 cc. Death occurred two weeks after admission.

DIFFERENTIAL DIAGNOSIS

DR. CHAMP LYONS: Dr. Bland, can you give us an interpretation of these electrocardiographic hieroglyphics?

DR. EDWARD F. BLAND: Yes; it is an abnormal record, the chief thing being left-axis deviation, which suggests some cause for strain on the left ventricle. The ST changes are, however, secondary to the axis deviation.

DR. LYONS: Dr. Hampton, should you like to comment on the x-ray films now?

DR. AUBREY O. HAMPTON: I am not very proud of these films. They all show motion. The patient was apparently unable to co-operate, and all the statements made in the record are probably based on insufficient evidence.

Is there anything that interests you very much?

DR. LYONS: I am particularly interested in the interpretation of the consolidation in the lungs.

DR. HAMPTON: As you can see, it is rather difficult to tell whether there is anything there or not. There is always more density along the left border of the heart when there is motion, and we may be making the mistake of calling that shadow pneumonia. I should think there is an area of consolidation in the left lung near the border of the heart. Small lesions diffusely scattered over the lung are not ruled out.

DR. BLAND: Is the left ventricle full?

DR. HAMPTON: Yes; the heart appears enlarged, particularly in the region of the left ventricle. I was trying to find the best film here of the psoas-muscle shadows. They were apparently interested

in the psoas muscles. The upper parts of both muscles are distinct. The lower portions fade out, but I do not believe we have enough evidence to suggest a psoas abscess. The kidneys appear large, and they do not function, as indicated by intravenous pyelogram.

DR. LYONS: This is the record of a sixty-five-year-old wool cutter with a progressive infection. His occupation suggests the possibility of anthrax, but all the cultural evidence indicates a staphylococcal infection.

Of interest in the past history are the stories of alcoholism, scarlet fever and progressive symptoms of heart failure during the last four years.

The immediate history is one of a neglected traumatic wound of the leg, which failed to heal, discharged pus, became ulcerated, and developed areas of hemorrhagic discoloration. One week before entry the patient suffered what I have interpreted as a pulmonary infarct.

On entry to the hospital he was dehydrated, with mild congestive failure and mild diabetes. A culture of the leg wound revealed *Staph. aureus* as the most probable pathogen. The absence of arterial pulsations in both lower extremities was indicative of peripheral arteriosclerosis and circulatory failure. The irregular but sharply demarcated zone of redness and hemorrhagic discoloration that did not blanch on pressure is of real interest. This is not the picture of erysipelas; the cultures failed to show a hemolytic streptococcus, and the patient should not have been very sensitive to erysipelas toxin because of the history of scarlet fever. The blood Hinton reaction is not reported, but tertiary syphilis is not a satisfactory explanation of this picture. A normal blood cevitic acid and prothrombin time and an absence of purpuric spots elsewhere make it likely that the skin changes were of local origin. I have interpreted these changes as the result of a venous thrombosis in an extremity with circulatory deficiency. This offers a logical explanation of the source of the pulmonary infarct described in the history and permits a hypothetical reconstruction of the course of events that led to the patient's death. I have reasoned that the thrombophlebitis was a septic staphylococcal thrombophlebitis and gave rise to the staphylococcemia necessary for the development of metastatic visceral abscesses present at the time of the second admission.

The enlarged liver and the development of jaundice after two days of sulfanilamide are extremely interesting. If the liver enlargement were on the basis of congestive failure, I should have expected it to be tender and associated with signs of pulmonary congestion. Amyloid disease does not ap-

pear likely because of the short history of sepsis. The history of alcoholism suggests that there may have been an alcoholic type of toxic cirrhosis. Jaundice developed coincidentally with the use of sulfanilamide and digitalis, and I believe that this was a toxic hepatitis in a cirrhotic liver.

At the time of the second admission the patient presented the problem of multiple abscesses and renal failure. A staphylococcal abscess of the prostate was drained, and the clinical signs of perinephric abscess on the left were present. The x-ray picture of consolidation was probably produced by septic pulmonary infarcts, which could have come from the prostatic venous plexus but more probably from the veins of the right leg. The blood culture post mortem should be positive for staphylococci. The location of other abscesses is largely a matter of conjecture on a statistical basis. There is no evidence in the record to establish a diagnosis of endocarditis, brain abscess or vertebral osteomyelitis. One or more small myocardial abscesses are extremely likely. My final diagnoses are: staphylococemia; extensive septic thrombophlebitis arising from the veins of the right leg; septic pulmonary infarcts; abscesses of the kidneys, heart and prostate; peripheral arteriosclerosis and arteriosclerotic heart disease; toxic cirrhosis of liver—alcoholic type; mild diabetes mellitus; and healed ulcer of leg.

CLINICAL DIAGNOSES

Cellulitis of left leg.
Carbuncle of buttocks.
Prostatic abscess.
Acute pyelonephritis.
Uremia.
Cirrhosis of liver.
Arteriosclerotic heart disease.

DR LYONS'S DIAGNOSES

Staphylococemia.
Extensive septic thrombophlebitis arising from the veins of the right leg.
Septic pulmonary infarcts.
Abscesses of the kidneys, heart and prostate.
Peripheral arteriosclerosis and arteriosclerotic heart disease.
Toxic cirrhosis of liver, alcoholic type.
Mild diabetes mellitus.
Healed ulcer of leg.

ANATOMICAL DIAGNOSES

Staphylococcal septicemia with abscesses in prostate, kidneys and lungs.
Ulceration of left lower leg.
Septic thrombophlebitis, left leg.
Septic infarction of the lungs.

Hypertrophy of the heart.
Biliary cirrhosis of the liver.
Cholelithiasis.

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: At the time of autopsy the major sepsis was localized in the kidneys. Both kidneys were very considerably enlarged and were studded with innumerable soft and large abscesses that had almost completely destroyed the parenchyma. I think the immediate cause of death was probably renal insufficiency rather than sepsis, although unquestionably both must have played a role. There were areas of septic infarction, with definite abscess formation in the lungs. The heart was enlarged, without an intrinsic lesion. The coronary arteries for his age were in quite good condition. I should think there was very little doubt that the hypertrophy went back to his known hypertension of many years' duration.

The liver was normal in size, and showed no evidence of abscess formation or chronic alcoholism. There was none of the fatty vacuolization that usually precedes an alcoholic cirrhosis. On the other hand, there was very slight but definite cirrhosis, and this was of the biliary type. There was proliferation of bile ducts and a significant inflammatory infiltration of the periportal connective tissue. Nothing in the history suggested gallstones, but the gall bladder did contain numerous faceted stones, and I should think that at some time in the past the patient must have had one or more stones in the common duct that caused some degree of obstruction and perhaps some retrograde infection. There was a considerable degree of inflammatory infiltration of the perinephritic tissues on both sides, a little more marked on the right, without, however, any frank perinephritic abscess. We were unable to determine the source of the septic emboli to the lungs. They might have come from either the leg vein or the periprostatic plexus. The sections showed a great many clusters of organisms resembling staphylococci in both lungs and kidneys.

DR HAMPTON: I should like to ask if anyone would consider ligating that vein if this situation occurred again.

DR LYONS: I should like to point out that, when the vein originally thrombosed, hemorrhagic discoloration appeared. We have done femoral-vein ligation for thrombosis in this age group without changing the course of events. The last patient died of gas bacillus infection with necrosis.

DR BENJAMIN CASTLEMAN: Your objection to ligation would apply only to septic phlebitis?

DR LYONS: Yes.

IN MEMORIAM: FREDERICK GRANT BANTING—EDWIN NELSON CLEAVES

FREDERICK GRANT BANTING, born on November 4, 1891, at Alliston, Ontario, was graduated in medicine from the University of Toronto in 1917 and soon was awarded the Military Cross for attending the wounded under fire at Cambrai, France. The world knows of his collaboration with a medical student, Charles H. Best, in the laboratory of Professor McLeod at the University of Toronto, of their joint discovery of insulin, announced in 1922, and of Banting's insistence that his half of the Nobel Prize, awarded in 1923, be shared with his co-worker, Best.

Known only to a small group is the Boston story, that of Edwin Nelson Cleaves, born in Med-

ford, Massachusetts, in 1890, and graduated from Harvard College in 1911 and from the Harvard Medical School in 1915; following graduation he was a surgical house-officer at the Massachusetts General Hospital.

It was while a house-officer, in 1916, that Cleaves, short of stature but of good physique, former captain of the Harvard Gymnastic Team, one hundred and forty pounds at his best weight, first discovered that he was excreting sugar. Becoming sugar-free on a comparatively liberal diet, he was resident and superintendent of the Out Patient Department of his hospital until the fall of 1918, when the great epidemic of influenza overwhelmed him. From that time on, his tolerance shattered, he existed on less than a thousand calories a day, weighing ninety-three pounds in his clothes when he went west in June, 1919.

In 1922 he was back in Boston, presumably for the last time, weighing eighty-three pounds, so weak that he had to be carried from his Pullman berth to the waiting stretcher. His books were audited and his accounts closed. He had fought a good fight and lost, although for months he had refused to acknowledge defeat.

At this point the lives of Banting and Best and of Cleaves met, and from then on his life was inseparable from their lives and accomplishments, for he received insulin and was among the first to be plucked by it from the grave's very brink. With health and vigor restored he returned to the fight and entered the field of roentgenology, became a member of various societies and made his own contributions to the science and the art of healing; he found relaxation and further service in work among the boys of Trinity Church. He, also, has appropriately been called a "hidden servant"; hidden only because of the narrow circle of his professional acquaintance.

Banting, continuing his scientific career, was knighted by King George V in 1934, re-entered the army, helped to establish Canadian blood banks and made important contributions to aviation medicine. Flying on a secret war mission to Britain he fell with his plane and companions, and died

in the snows of Newfoundland on February 21, 1941.

Three days later, Cleaves went to join his particular savior, working almost to the last, the victim of a nondiabetic disease, and the victor over diabetes for more than twenty-five years.

EARLY DIAGNOSIS OF TUBERCULOSIS

THE nation-wide Early Diagnosis Campaign being held throughout April by the National Tuberculosis Association and its affiliated state and local associations deserves the serious attention of every person who appreciates the need of conserving life, time, energy and money in these fateful days. Early diagnosis means a saving in lives and money. Since most cases of tuberculosis are taken care of in tax-supported institutions, and since it may take years to restore a patient with advanced tuberculosis to health,—if, indeed, cure is possible,—hospitalization of advanced cases results in a tremendous burden on the community; whereas, the early case usually is easily cured in a short time at a small cost. Year after year the public must be stirred up and made aware of the continuing threat of tuberculosis, which has lost none of its power to destroy or handicap the patient, although many fewer persons are threatened each year.

Since it is difficult to sustain interest and support in day-after-day efforts to educate the masses of people, it is well to concentrate effort and interest in a particular month. When people hear tuberculosis discussed on the radio, read articles about it in national magazines and local newspapers, and learn important facts about it from exhibits in store windows, they begin to realize that this disease is still a very serious menace. Complacency is displaced by interest and understanding and a better attitude toward the problem.

In addition to the literature provided by tuberculosis associations this year for various groups of the general public, including community leaders, educators, young, middle-aged and old people, and factory workers, a new publication is available to physicians. This brochure, entitled *Chest X-Ray Interpretation*, was written by Dr. J. Burns

Amberson, Jr., and has been published by the National Tuberculosis Association.

The theme for this year's campaign is, "A Good X-Ray is Your Doctor's Best Aid in Discovering Early Tuberculosis." This slogan should lead both those who suspect they have tuberculosis, and those who have no symptoms but want a thorough health check-up, to go to their physicians with the expectation that chest x-ray films will be taken.

The present development of technics and equipment for mass x-ray studies with less expensive film hastens the time when apparently healthy persons will be examined in large numbers. Until such time, education must be relied on to convince people who most need x-ray study that they should use existing services.

OBITUARY

GEORGE LINCOLN WALTON

1854 - 1941

In the death of George Lincoln Walton on January 17, the Boston Society of Psychiatry and Neurology lost its oldest living member. Dr. Walton's name is doubtless only a memory to most of those present, for he ceased practice in 1916; even to the writers his early activities are shrouded in tradition, and acquaintance was based more on the happy philosophy that radiated from him in social contact, than on factual discussion in the clinic.

Dr. Walton's early interests in neurology were varied. At the turn of the century, the neurologist was equally interested in the functional and the organic diseases of the nervous system. His papers, of which there are three large volumes at the Harvard Medical School, show an interest in both, but emphasize especially structural diseases and their diagnostic signs. Even in 1900 a paper written in collaboration with Dr. W. E. Paul, commending, on the basis of much clinical study, the value of the Babinski reflex, was a novelty. His successful attempts at localization of tumors of the brain and spinal cord are duly registered, and his usefulness to the surgeon is apparent. A letter from the elder John Homans in reminiscent vein denotes the significant relation of neurologist and surgeon of that time: "I remember your dancing round the operating room—I swear it—and saying that you had waited twenty-five years for this moment, that you had made diagnoses and that no surgeon could take the tumor out."

Perhaps his main contribution to structural neurology concerns dislocation of the cervical vertebrae and the manipulation that he devised for reduction; this was in the days of observation and palpation, with no help from x-ray films.

Many of Dr. Walton's early papers deal with hysteria. Doubtless his name is most closely linked with three small popular books on psychotherapy. Many a person received help from these simple, often whimsical, yet erudite treatises on the various aspects of psychoneurosis, and one at least — *Why Worry* — ran to twenty-three printings. Those were the days of exhortation, of reasoning and of reassurance. Psychoanalysis had not been heard of, and when it came was not approved by Dr. Walton.

But it is as a happy man of resource that we like to think of him: always eager, always courteous and helpful both in word and deed. His retirement from active practice in 1916 at the age of sixty-two gave him, unlike most men, the time he had looked forward to for the hobbies that he had always advocated for others. During the subsequent twenty-five years these avocations embraced many intellectual fields, in two of which Dr. Walton became more than an amateur. He collected old silver, some pieces of which are now in the Museum of Fine Arts; he became an excellent photographer; he studied certain aspects of archaeology and gave to the Warren Museum an exhibition illustrating burial customs of ancient Egypt. History, especially historical facts, intrigued him, and his writings give evidence of this interest. A botanical work *The Flower Finder*, first published in 1914, went through four editions to 1935, and is still an approved guidebook, based on his own classification — that of color rather than of family.

With all his scientific and cultural interests, his wit, as shown in his conversation and in his writing, runs throughout, and his occasional poems, read before gatherings of the American Neurological Association and of the Chakara Club and elsewhere, disclose the gay yet serious qualities of his mind.

Dr. Walton's death breaks a link with our intellectual past. We mourn this fact. We acclaim his success.

MEDICAL EPONYM

HENLE'S LOOP

This anatomic structure was described by Friedrich Gustav Jacob Henle (1809–1885), professor of anatomy at Göttingen in his *Handbuch der sys-*

tematischen Anatomie des Menschen (Vol. II, p. 303; Braunschweig, 1862). A portion of the translation follows:

The narrow canaliculae are always found in the interstices between the larger ones, running parallel with them and showing no tendency whatever to join them. Instead, they terminate at various levels, the lowest immediately under the surface of the papillae in the bridges between the larger canals, and are blind in the sense that two neighboring canaliculae join together in a sharp loop. Because of this course I have given them the name of loop-shaped canaliculae.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON STATE AND NATIONAL LEGISLATION

House Bill 1477, the enabling act for medical-costs insurance sponsored by the Society, has been passed by the Committee on Insurance, and the House Counsel has written an emergency preamble to the bill. It has received a new number, becoming House Bill 2301, and has been sent to the House Committee on Ways and Means. No date has yet been set by that committee for a hearing on the bill, but all members of the Society should get in touch with members of that committee who are from their districts and ask them to act favorably and promptly on the bill. The list of members of the House Committee on Ways and Means, with their addresses, appeared in the March 20 issue of the *Journal*. All representatives and senators not on the committee should be requested to appear before the committee and register their approval of the bill.

HYPERTENSION ASSOCIATED WITH PREGNANCY AND RESULTING IN PREMATURE DELIVERY AND FATAL POST-PARTUM CONVULSIONS

A twenty-nine-year-old para IV was first seen very early in her pregnancy by her family physician. At that time her blood pressure was 180 systolic, 110 diastolic, and her weight was over 200 pounds.

At fourteen years of age, the patient had had a

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

blood pressure of 190 systolic. There was no history of scarlet fever or of kidney disease. The first pregnancy resulted in a normal delivery of a living child, the second and third pregnancies were terminated by miscarriage.

Physical examination at the time of her first visit was negative except for the aforementioned blood pressure and obesity. The lungs were clear and resonant; there were no rales. A therapeutic abortion was advised and refused.

The patient was seen routinely and was put to bed when five months pregnant. During this time her blood pressure ranged between 200 and 80 systolic, 120 and 110 diastolic. She started in spontaneous labor when she was just over eight months pregnant and delivered normally a living child. One hour later the first of five convulsions occurred, and three and a half hours after delivery the patient died. The baby died a week later of prematurity.

Comment. This is a case of hypertension, probably nephritic in origin and of at least fifteen years' duration, which resulted in premature birth and post-partum convulsions. Whether these convulsions could be called eclampsia or whether they were uremic convulsions due to an underlying chronic nephritis is debatable. The usual case of eclampsia develops in women who have normal blood pressure at the beginning of pregnancy.

Hypertension of this degree—200 systolic, 120 diastolic—at the onset is a grave condition, and conservatism indicates the interruption of pregnancy. In this particular case, the suggestion of interruption was made, but the patient refused. She was treated adequately with rest in bed after the fifth month; frequent urinalyses were carefully carried out, and a proper diet was prescribed, but the outcome was only what one might have expected.

Premature labor is a common occurrence in cases of hypertension. Intrauterine death frequently precedes premature labor, and when this occurs the patient often improves symptomatically. Obstetrically, it might have been wise to have delivered this woman as soon as it was believed that the baby was viable. The possibility of her going to term and surviving with a blood pressure of this sort from the beginning was extremely unlikely.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 20:

BERKSHIRE

Thursday, April 24, at 4:30 p.m., in the Bishop Memorial Building, Pittsfield. *Obstetric Infections: Diagnosis and treatment.* Instructor: Joseph W. O'Connor. Harry G. Mellen, *Chairman.*

BRISTOL SOUTH (Fall River Section)

Tuesday, April 22, at 4:30 p.m., at the Union Hospital, Fall River. *Diagnosis and Treatment of Minor Lesions of Rectum and Anus.* Instructor: Franklin G. Balch, Jr. Howard P. Sawyer, *Chairman.*

FRANKLIN

Thursday, April 24, at 8:00 p.m., in the Library of the Franklin County Public Hospital, Greenfield. *Acute Abdominal Pain: Its interpretation and management.* Instructor: Stanley J. G. Nowak. Halbert G. Stetson, *Chairman.*

HAMPDEN

Wednesday, April 23, at 4:00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8:00 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. *Pediatric Case Discussions.* Instructor: Edwin H. Place. Alfonso A. Palermo, *Chairman.*

HAMPSHIRE

Thursday, April 24, at 4:15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. *Therapeutic Uses of Preparations of Endocrine Glands: Thyroid gland, pituitary gland, ovary, testis and adrenal cortex.* Instructor: Harry B. Friedgood. Robert C. Byrne, *Chairman.*

WORCESTER

Tuesday, April 22, at 8:30 p.m., in the Nurses' Home of the Milford Hospital, Milford. *Chemotherapy in the Treatment of Gonococcal Infection.* Instructor: Weston T. Buddington. Joseph Ashkins, *Chairman.*

WORCESTER NORTH

Friday, April 25, at 4:30 p.m., in the Nurses' Home of the Burbank Hospital, Fitchburg. *Dermatitis and Eczema.* Instructor: Mildred L. Ryan. George P. Keaveny, *Chairman.*

THE EGO: NERVES AND SELFISHNESS*

Mental hygiene, maladjustment, "nerves" and nervous breakdowns are so much talked about and written about these days that we may well be somewhat bewildered in trying to understand and to know what to believe. Most of us have become more and more conscious of the fact that we can feel nervous, unhappy or even sick without any physical disease. We are told that our emotions or mental conflicts can cause nervousness in its many forms. And furthermore we are advised that we may not even be aware of what is making us nervous, because the seat of our troubles may be in our unconscious minds. Unconscious or subconscious desires or conflicts are pointed to

*A "Green Lights to Health" broadcast given through station WAAB by Dr. Vernon F. Williams on Wednesday, January 29, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

as the origin of our jitters, our gloomy moods, our restlessness, unhappiness and so forth.

Now, this so-called "discovery" of modern science—that unconscious motives may be responsible for the way we act and the way we think and feel—can be quite disturbing if not frightening. We may be at a loss to know what awful forces or ideas have us in their power, and even if we try to find out we may not be sure that we have the right answer.

In maintaining or regaining a reasonable degree of mental health, it may not always be necessary to ask for the aid of a specialist in psychology. Even though it is true, as it certainly is, that we can get into trouble because of motives and tendencies of which we may be unaware, we should not let ourselves off too easily with the partially comforting thought that we are not responsible because we are in the grip of our mysterious unconscious minds. If we are willing to face the facts,—and it is healthy to do so,—we can frequently see wherein our difficulties lie.

Today the subject to be discussed is related to one very important part of the structure of the human personality—a part that is so obviously present in all of us that it should not require the expert help of a psychiatrist to make us aware of its existence. It is powerful and forceful, and we may not always be aware of its presence and yet even a moderate amount of self-examination by a person of average intelligence will convince us that the depths of human personality do not have to be plumbed to discover it. This part of us may be called "the ego."

You know that in all of us there are deep, instinctive drives or forces that have to do with our well being. We have bones to support the other tissues of our bodies. We have hearts to pump the oxygen-carrying blood through our bodies, and we have instinctive forces, which in complicated ways enable us to adjust ourselves to and hold our own in an external world that makes all sorts of demands on us. Now what is called the ego is the urge to protect ourselves and to make our way through life with as little harm or injury to ourselves as possible. It is the same force that makes the housefly try to avoid the swatter or the bird in the street avoid the oncoming automobile. But it is more than that: it is also the force that inclines us to get as much as we can for ourselves. It gives us our ambition, our desire to excel or at least to be as good as anybody else in the many situations that develop from our contacts with other human beings. It is the force that tends to make us see ourselves in as favorable a light as possible and to close our eyes to our shortcomings. And sometimes, unfortunately, it is the force from which comes an insatiable craving for power. I refer not only to a would-be world conqueror, but also to anyone who does not have the sense to limit his desires for dominance or pre-eminence in all the various directions in which his interests may lie.

Now, this ego drive or force is surely behind much of our behavior, and is consequently related to some of our deepest feelings and motives. One may say, "What of it? Isn't it good and natural to want to protect and develop oneself?" Of course it is, but the trouble is that unless this ego drive is controlled by reason and intelligence, it may get out of hand and lead us into difficulties. And one of the common difficulties is nervousness in some form or other.

If we have become accustomed to obtaining what we want and then at a certain point find that our aggrandizing desires are blocked because of circumstances or because they come into conflict with what other people want, we are apt to feel frustrated and unhappy unless we have the judgment to know that it is good that there should be a

limit to our egotistic advances. And it is a fact that nervous symptoms may arise when we feel frustrated.

It is easy for us to see the importance of checking this ego drive when we are considering other people. We all know that it is common sense to curb a selfish child before he develops tantrums when he cannot have what he wants. It may not be quite so easy to see selfishness in ourselves when we are upset because our wives or husbands are not so considerate of us as we think they should be. When we are offended, it is wise to consider whether or not we too may sometimes say or do things that may be displeasing. Also we might keep in mind the possibility that we may be unhealthily sensitive or that the person who makes unpleasant remarks may himself be suffering from a maladjustment that will not be cured by counterattack.

We are inclined to be so self-protective that unless we are wise or big-hearted or generous in our feelings toward other people we react instinctively to being rubbed the wrong way. If we are offended, insulted or neglected by anyone whose attitude affects us, the tendency is to hit back, to become resentful, to bear a grudge or to brood gloomily over the offence. This is no recent discovery. Christ pointed it out when he made the suggestion about turning the other cheek. Even that fictitious creature, the cold-blooded scientist, is not immune to this self-protective reaction. It is natural to respond to and to feel friendly toward people who respond to us, or who at least do not step on our particular mental corns.

We may or may not be aware of it, but one of our first reactions in meeting people is to sense whether or not they like us or give us due consideration. Many a friendship of years' standing, founded perhaps on not too solid a basis, may be threatened or broken by a too-frank criticism of our weaknesses. Someone has said that one sign of being a mature person is having the tact not to tell our friends things about themselves that we know they do not want to hear.

Such is the nature of the ego that the memory of a slight or a hurt may continue for years. On certain occasions,—when the warmth of friendliness or sometimes the warmth of alcohol, may induce it,—one person may tell another that the only thing he has ever held against him was the time when he said thus and so—always a body blow to his self-esteem.

We do not like to think of our frailties, and we are not likely to welcome other people bringing them up for discussion. It is, of course, not healthy to be morbidly introspective, to brood over one's shortcomings, and it is not suggested that we follow such a pursuit. But it is well to consider whether or not our egos, our selfish aims, may not need investigating when we find that we are in trouble with ourselves, other people or our environments. The selfish person is not inclined to spend much time thinking of his selfishness; if he were, he might try to do something to correct it. However, one need not be predominantly selfish to have ego trouble in some direction. A man may be quite unselfish toward his wife and children and yet be jealous of someone with whom he thinks he is in competition in his office. Or he may be entirely too possessive with his wife or children and nevertheless have a very fair and co-operative spirit with his business associates. It is interesting to note that the seventeenth century French writer, the Duke de la Rochefoucauld, whom Byron called "Nature's sternest painter, yet the best," saw so piercingly into the human ego that his writings were at various times suppressed.

The self-protective ego manifests itself in many ways.

Sometimes we see it in the form of gossip or criticism of other people. The criticism is frequently of people whom we know in our hearts to be superior to us in certain respects, or of people who have done us a hurt. The criticism is a cheap leveling process by which we try to compensate for our feelings of inferiority.

Now perhaps all this sounds too simple, too obvious. After all, everyone knows that those who live in glass houses should not throw stones—this was said, of course, before the invention of the substantial, modern glass house. Everyone knows that we are more likely to see the mote in our brother's eye than to be aware of the beam in our own. But let us not be too sure that the things that are obvious can be dismissed as lacking in profundity. In modern scientific investigation of the human mind there is too often a tendency to discard the obvious as being superficial. And yet up to the present, science has discovered nothing more fundamental than the human ego.

Even the sex impulse has not been proved to be so important. It is claimed by some investigators of human behavior that some maladjustment of the sexual instinct is always the primary cause of neurotic difficulties. This can scarcely be so when we know that two people may like each other tremendously, although not at all attracted sexually. Also, it is a fact that many husbands and wives who are not particularly compatible sexually have happy and on the whole satisfactory married lives. If two people care enough about each other and about something beyond their own physical satisfaction, they can have a good and contented life together in spite of lack of sexual compatibility.*

It is true that sexual frustration, together with frustration of the desire for just the right amount and kind of affection and understanding, can be very hard to face calmly and cheerfully, and yet if we do not have it in our heads, through overemphasis, that we must have this satisfaction, we can go along very well, it has been done again and again.

It should not be concluded from this discussion of the ego that a meek, self-effacing attitude is healthy or desirable. Some people give in too easily. They do not as yet take themselves enough, and there are always others who seek advantage of those whom they can dominate. But analysis of people's difficulties shows repeatedly that a person can become nervous and unhappy because of a thwarting or frustration of his wants and desires. If we stop to think that we cannot have everything we want and cannot expect other people to be entirely as we should like to have them, the insight gained will help to dispel the emotional upheaval that is making us sick.

There need not be anything especially mysterious or unfathomable in many of our troubles if we are willing to do a little self-examination. If we are having ego trouble in relations with other people, the secret is to go a few steps farther than the other person in self-criticism, tolerance and understanding, rather than become aggressive or resentful.

Q If we are as self-protective as you suggest, I should think it would be very difficult for us to admit that our troubles are due to egotism.

A It may well be. People differ greatly in how willing they are to be frank with themselves, and again, so powerful and blind may the ego be that it seems practically impossible for some to admit that they may be wrong. But the ego drive does not have to be self-destructive. Since its very nature is to protect the personality through

intelligence and reason, this protection can be farsighted and wise. Willfulness of the moment can be sacrificed for healthy gain in the long run.

Q Would it be called selfish to strive to do one's best in one's work or profession and not to give in to obstacles?

A Not necessarily, but it is wise to remember that we all have limitations, and if nervous symptoms develop along with our striving we should consider whether or not egotistic ambition is impelling us beyond our abilities.

Q In relations between people, I should think it would be hard to know when it is right to assert oneself so that one is not being stepped on, and when one should tolerate by hold one's tongue.

A That should depend on whether one is hitting back because some weakness in oneself, which one does not like to face, has been touched, or whether the offending statement is objectively untrue. Most frequently the soft answer is good policy. Notice that policemen frequently quiet down when their outbursts do not get an angry response. We should be able to have an inner strength and self-possession founded on adequate self-knowledge. Hitting back with words or acts is then much less likely to occur, and that would in no way be a sign of moral or character weakness.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR FEBRUARY, 1941

DISEASES	FEBRUARY 1941	FEBRUARY 1940	FIVE YEAR AVERAGE*
Anterior polio myelitis	0	2	0
Chicken pox	1103	1 02	1463
Diphtheria	6	13	16
Dog bite	537	630	566
Dysentery bacillary	12	41	15
German measles	89	60	141
Gonorrhea	287	291	369
Lobar pneumonia	463	5 9	695
Measles	1896	1191	2360
Meningococcus men ng 178	8	5	12
Mumps	696	668	1043
Paratyphoid B fever	4	1	1
Scarlet fever	531	509	941
Syphilis	344	405	429
Tuberculosis pulmonary	192	1 9	184
Tuberculosis other forms	13	30	22
Typhoid fever	3	5	5
Undulant fever	5	4	3
Whooping cough	931	532	828

*Based on figures for preceding five years

RARE DISEASES

Anthrax was reported from Malden, 1 (delayed report), total, 1.

Diphtheria was reported from Chelsea, 2, Natick, 1, Peabody, 1, Rehoboth, 1, Waltham, 1, total, 6.

Dysentery, bacillary, was reported from Belmont, 4, Danvers, 3, Cambridge, 1, Holliston, 4, total, 12.

Infectious encephalitis was reported from Attleboro, 1, total, 1.

Malária (therapeutic) was reported from Foxboro, 5, total, 5.

Meningococcus meningitis was reported from Brn stable, 1, Boston, 1, Fairhaven, 1, Groton, 1, Hopedale, 1, New Bedford, 1, Northbridge, 1, Waltham, 1, total, 8.

Paratyphoid B fever was reported from Chelmsford, 1, Norwood, 1, Salem, 2, total, 4.

Pellagra was reported from Boston, 2, total, 2.

Septic sore throat was reported from Bernardston, 3,

*This and the subsequent paragraph were omitted in the broadcast.

Boston, 9; Chelsea, 1; Fall River, 2; Holyoke, 1; Lynn, 1; Medford, 1; Merrimac, 1; Newton, 1; Norfolk, 1; Peabody, 1; Revere, 2; Winchester, 1; Wrentham, 1; total, 26.

Tetanus was reported from: Concord, 1; total, 1.

Trachoma was reported from: Boston, 2; Cambridge, 1; Springfield, 1; total, 4.

Trichinosis was reported from: Boston, 1; Framingham, 4; Southbridge, 1; total, 6.

Typhoid fever was reported from: Boston, 1; Cambridge, 1; Medford, 1; total, 3.

Undulant fever was reported from: Brockton, 1; Montague, 1; Palmer, 1; Reading, 1; Wayland, 1; total, 5.

Undulant fever, paratyphoid B fever, tuberculosis (pulmonary) and whooping cough were reported above the five-year averages.

Chicken pox was reported at the lowest figure since the corresponding month in 1932.

Diphtheria hit a record low figure for February.

Dog bite was reported at the lowest figure for this month since 1938.

German measles, gonorrhea, measles, meningococcus meningitis, mumps, scarlet fever, tuberculosis (other forms) and typhoid fever were reported below the five-year averages.

Lobar pneumonia showed a record low figure for the month.

NOTICES

BOSTON CITY HOSPITAL ALUMNI DAY

Boston City Hospital Alumni Day will be celebrated on Saturday, April 26.

PROGRAM

10:30 a.m.—12:30 p.m. Dry clinic, Cheever Amphitheater.

Carcinoma of the Large Bowel and Rectum. Dr. Frank H. Lahey.

Some Bizarre Forms Taken by Contagious Diseases. Dr. Edwin H. Place.

Progress in Gynecology and Obstetrics. Dr. Frederick L. Good.

Enlargement of the Spleen. Dr. William B. Castle.

Nature and Treatment of Pulmonary Edema. Dr. Soma Weiss.

12:45 Luncheon at the hospital.

7:00 p.m. Dinner at the University Club.

Professor Bruce Hopper, of Harvard University, will be the guest speaker.

In the afternoon, there will be a choice of seeing the Red Sox game at Fenway Park or playing golf at the Belmont Country Club.

BOSTON HEALTH LEAGUE

The annual meeting of the Boston Health League will be held at Perkins Hall, Women's Educational and Industrial Union, 264 Boylston Street, Boston, on Wednesday, April 23, at 12:30 p.m. Dr. G. Lynde Gately will speak on "Activities of the Health Department of the City of Boston."

The charge for luncheon will be 75 cents. Reservations, sent to the Boston Health League, Inc., 80 Federal Street, Boston, should be made by Monday, April 21.

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, April 29, at 5 p.m.

PROGRAM

Observations on the Blocking Antibody in the Treatment of Hay Fever. Dr. Francis M. Rackemann and Miss Margaret Scully.

The Production of Hypothyroidism in Rabbits by the Injection of Thyroglobulin: Its relation to refractoriness. Dr. Jacob Lerman.

Roentgen Diagnosis of Primary Carcinoma of the Liver. Dr. Richard Schatzki.

MASSACHUSETTS SOCIETY FOR SOCIAL HYGIENE

The annual meeting of the Massachusetts Society for Social Hygiene will be held on Friday, April 25, at 4 p.m. in the Hotel Sheraton, 91 Bay State Road, Boston. The keynote of the program will be social hygiene and national defense. Brief reports will be given by Dr. George Gilbert Smith, president, and Mr. Richard H. Anthony, field representative in charge of the defense program of the society.

PROGRAM

The Soldier on Leave in Boston. Hon. Joseph Timilty, police commissioner of Boston.

Citizen Responsibility in National Defense from the Viewpoint of the Navy. Capt. Charles S. Stephenson, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Following the program, tea will be served. The public is cordially invited to attend.

WALTHAM MEDICAL MEETING

There will be a clinicopathological staff conference of the Metropolitan State Hospital on Wednesday, April 30, at 8 p.m. A case of hemiplegia and aphasia will be presented by Drs. E. V. Semrad and R. C. Wadsworth. It will be discussed by Dr. Kurt Goldstein.

All interested physicians are cordially invited to attend.

ESSEX NORTH DISTRICT MEDICAL SOCIETY

The Essex North District Medical Society will celebrate its one hundredth anniversary on Wednesday, May 7, in Lawrence, Massachusetts. The centennial committee has prepared an interesting program for the day.

The annual business meeting of the district society will be followed by an inspection of hospitals of the city and a visit to the various textile plants. There will be a display of old photographs, instruments and manuscripts of historical significance in regard to the past one hundred years of the district society. The annual dinner will be held in the evening, at which time Dr. Walter G. Philip, president of the Massachusetts Medical Society, and Dr. Frank H. Lahey, president-elect of the American Medical Association, will be the guest speakers. A group of fellows of the society, under the direction of Dr. Benjamin Spector, will present three dramatizations of important medical events that have occurred in the past one hundred years.

The ladies of the district have prepared an interesting afternoon for the wives of the members.

Essex North District Medical Society cordially invites members of the Massachusetts Medical Society to be present at this meeting. Reservations may be secured by writing to the secretary of the district, Dr. H. R. Kurth, 477 Essex Street, Lawrence.

WORCESTER NORTH DISTRICT MEDICAL SOCIETY

The eighty-second annual meeting of the Worcester North District Medical Society will be held at the Burbank Hospital, Fitchburg, on Wednesday, April 23.

PROGRAM

- 10.00 a.m. Gonadogen (medical film).
 11.00 a.m. Treatment of General Peritonitis. Dr. Thomas J. Anglem, of the Massachusetts Memorial Hospitals.
 11.30 a.m. Carcinoma of the Lung. Dr. John W. Strieder, of the Massachusetts Memorial Hospitals.
 12.00 m. Recent Advances in Medical Therapy. Dr. Clifford L. Derick, of the Peter Bent Brigham Hospital.
 12.30 p.m. Vitamin B Deficiency (medical film).
 1.00 p.m. Recent Advances in Infant Feeding and Therapy. Dr. Edwin T. Wyman, of the Children's Hospital, Boston.
 1.30 p.m. Indications for Cesarean Section. Dr. Joseph W. O'Connor, of the Worcester Memorial Hospital.
 2.00 p.m. Dinner in the Nurses' Dining Room, Burbank Hospital.

UNITED STATES CIVIL SERVICE EXAMINATION

Psychiatric and Social Case Workers, \$2000 a Year

There are now opportunities for social workers to enter governmental service as psychiatric or social case workers. Vacancies exist in the Veterans' Administration and in the Bureau of Prisons of the Department of Justice. An examination to fill these positions has been announced by the United States Civil Service Commission. The salary is \$2000 a year.

Persons appointed in the Veterans' Administration will do psychiatric social work. In the hospitals and the regional offices of the Administration they will study patients' social needs to facilitate the medical diagnosis and treatment of the patients. Persons appointed in the Bureau of Prisons will act as social case workers in federal penal and correctional institutions. They will interview inmates and secure social data concerning them, and will co-operate with social agencies and federal probation officers on family needs and other factors affecting the inmates' adjustment. They will also follow through their duties by drafting plans for the inmates' release and subsequent readjustment.

A written test will not be given, but applicants must submit reports and writings as corroborative evidence of their training. They must have completed a four-year college course that included or was supplemented by one year of graduate or undergraduate study with a minimum of three hundred hours of supervised field work in an accredited school of social work. In addition, for positions in the Veterans' Administration, six semester hours' credit in psychiatric social work is required; and for positions in the Bureau of Prisons, six semester hours' credit in the methods of dealing with delinquent behavior.

Applications must be filed with the Commission's Washington office not later than May 14, 1941. Further

information and application forms may be obtained at any first-class or second-class post office or from the Civil Service Commission.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 20

MONDAY, APRIL 21

American College of Physicians Hotel Statler, Boston
 12 15-1 15 p.m. Clinicopathological conference Peter Bent Brigham Hospital amphitheater.

TUESDAY, APRIL 22

American College of Physicians Hotel Statler, Boston
 12 15-1 15 p.m. Clinicomorphogenologic conference Peter Bent Brigham Hospital amphitheater

WEDNESDAY, APRIL 23

American College of Physicians Hotel Statler, Boston
 *12 m Clinicopathological conference Children's Hospital.
 12 30 p.m. Activities of the Health Department of the City of Boston, Dr. G. Lynde Gately Boston Health League Perkins Hall, Women's Educational and Industrial Union 264 Boylston Street, Boston.

THURSDAY, APRIL 24

American College of Physicians Hotel Statler, Boston

FRIDAY, APRIL 25

American College of Physicians Hotel Statler, Boston
 14 p.m. Massachusetts Society for Social Hygiene Hotel Sheraton, 91 Day State Road, Boston
 8 15 p.m. Massachusetts Memorial Hospitals, staff meeting Evans Memorial auditorium

SATURDAY, APRIL 26

Boston City Hospital Alumni Day

*Open to the medical profession

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Macleod's Physiology in Modern Medicine. Edited by Philip Bard, Ph.D., professor of physiology, Johns Hopkins University School of Medicine. With collaboration of Henry C. Bazett, M.D., L.R.C.P., professor of physiology, University of Pennsylvania; George R. Cowgill, Ph.D., associate professor of physiological chemistry, Yale University School of Medicine; Howard J. Curtis, Ph.D., instructor in physiology, Johns Hopkins University School of Medicine; Harry Eagle, M.D., lecturer in medicine, Johns Hopkins University School of Medicine; Chalmers L. Gemmill, M.D., associate in physiology, Johns Hopkins University School of Medicine; Magnus I. Gregersen, Ph.D., professor of physiology, College of Physicians and Surgeons, Columbia University; Roy G. Hoskins, Ph.D., M.D., director of research, Memorial Foundation for Neuroendocrine Research, and research associate in physiology, Harvard Medical School; J. M. D. Olmsted, Ph.D., professor of physiology, University of California; and Carl F. Schmidt, M.D., professor of pharmacology, University of Pennsylvania. Ninth edition. 8°, cloth, 1256 pp., with 124 tables and 387 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$10.00.

America Organizes Medicine. By Michael M. Davis, Ph.D., chairman, Committee on Research in Medical Economics. 8°, cloth, 335 pp. New York and London: Harper and Brothers, 1941. \$3.00.

The Chemical Action of Ultraviolet Rays. By Carleton Ellis, B.S., and Alfred A. Wells. Revised and enlarged edition by Francis F. Heyroth, M.D., Ph.D., University of Cincinnati. 8°, cloth, 961 pp., with 159 illustrations. New York: Reinhold Publishing Corporation, 1941. \$12.00.

Wolf Child and Human Child: Being a narrative interpretation of the life history of Kamala, the wolf girl. By Arnold Gesell, M.D., Yale University. 4°, cloth, 107 pp. New York: Harper and Brothers, 1941. \$2.00.

Diseases Transmitted from Animals to Man. By Thomas G. Hull, Ph.D., director, The Scientific Exhibit, American Medical Association. Second edition. 8°, cloth, 403 pp., with 45 illustrations. Springfield, Illinois: Charles C Thomas, 1941. \$5.50.

Hemorrhagic Diseases: Photo-electric study of blood coagulability. By Kaare K. Nygaard, M.D., fellow of the Alexander Malthe Foundation for Research in Medicine, Surgery and Gynecology. 8°, cloth, 320 pp., with 59 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$5.50.

The New International Clinics: Original contributions, clinics, and evaluated reviews of current advances in the medical arts. Edited by George Morris Piersol, M.D., professor of medicine, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Vol. 1, N. S. 4, 1941. 8°, cloth, 304 pp., with 44 illustrations, and 19 tables. Philadelphia: J. B. Lippincott Company, 1941. \$3.00.

Manual of Clinical Chemistry. By Miriam Reiner, M.Sc., assistant chemist, Mount Sinai Hospital, New York. Introduction by Harry Sobotka, Ph.D., chemist, Mount Sinai Hospital. 12°, cloth, 296 pp. New York: Interscience Publishers, Incorporated, 1941. \$3.00.

An Introduction to Dermatology. By Richard L. Sutton, M.D., Sc.D., LL.D., F.R.S. (Edin.), emeritus professor of dermatology, University of Kansas School of Medicine; and Richard L. Sutton, Jr., M.D., L.R.C.P. (Edin.), assistant professor of dermatology, University of Kansas School of Medicine. Fourth edition. 8°, cloth, 904 pp., with 723 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$9.00.

American Gynecological Society Transactions. Vol. 65 (1940). Edited by Richard W. TeLinde, M.D. 8°, cloth, 241 pp., with 77 figures and 73 tables. St. Louis: The C. V. Mosby Company, 1941.

Spermatozoa and Sterility: A clinical manual. By Abner I. Weisman, M.D., adjunct gynecologist, Jewish Memorial Hospital, and clinical assistant visiting gynecologist and obstetrician, Metropolitan Hospital, New York. With a foreword by Robert L. Dickinson, M.D. 8°, cloth, 314 pp., with 70 illustrations. New York: Paul B. Hoeber, Incorporated, 1941. \$5.50.

Blood Transfusion Association: Report concerning the project for supplying blood plasma to England. Narrative account of work and medical report. 8°, paper, 21 pp. New York: Blood Transfusion Association, 1941.

Surgery of Modern Warfare. Vol. I. By sixty-five contributors. Edited by Hamilton Bailey, F.R.C.S.; surgeon, Royal Northern Hospital, London. 4°, cloth, 480 pp., with 502 illustrations. Baltimore: Williams and Wilkins Company, 1941. \$10.00.

BOOK REVIEW

The Chinese Way in Medicine. By Edward H. Hunt, M.D. 8°, cloth, 189 pp., with 8 illustrations. Baltimore: Johns Hopkins Press, 1940. \$2.25.

This stimulating little volume seeks to place before the reader a rapid survey of a system of medical thought that is philosophical in conception and has proved adequate for the needs of an eastern Asiatic civilization.

The three lectures that form the basis for this book are: "The Universe and Man in Chinese Medicine," "The Founders and Chief Exemplars of Chinese Medicine," and "Some Distinctive Contributions of Chinese Medicine." The author develops in an admirable manner the three characteristic approaches of the Chinese way in medicine—the cosmic, the animistic and the medicamental. The thesis is presented that the Chinese have made significant contributions in the fields of medical literature, medicaments, physical therapy and diagnostic methods. Although this book may make its appeal to a strictly professional group, it is to be highly recommended to students in colleges of liberal arts, as well as to those in medical schools.

NUMBER 17

TUBERCULOUS INFECTION AMONG NURSES AND MEDICAL STUDENTS IN SANATORIA AND GENERAL HOSPITALS

PAUL DUFALT, MD†

RUTLAND, MASSACHUSETTS

THE fear of contagion from tuberculosis among medical workers is far from recent. Val salva, who lived from 1666 to 1723, avoided autopsies of those dying from phthisis, because he was afraid of contracting the disease. Morgagni did likewise to protect himself and his pupils from exposure. Laennec, who died from tuberculosis, was convinced that he had acquired his illness while doing post mortem examinations. In the middle of the last century, French army surgeons had already observed the high incidence of tuberculosis among the orderlies of the military hospitals in times of peace.

These clinical observations were to receive their scientific confirmation in 1865, when Villemin recognized the transmissibility of tuberculosis, and their undeniable proof in 1882, when Koch announced to the world the discovery of the tubercle bacillus. In that year, pulmonary tuberculosis entered automatically into the rapidly growing class of contagious diseases.

The medical profession, however, was slow to adopt a logical attitude toward the adequate protection of all those entrusted with the care of tuberculous patients. Not that some of its members were not aware of the possibilities of infection. On the contrary, as early as 1889, Cornet¹ reported on the epidemiology of tuberculosis in the German Catholic nursing orders for twenty-five years and found the death rate from that disease exceedingly high, especially among the young nuns. "A girl of seventeen," he wrote, "devoting herself to hospital nursing died on the average twenty-one and a half years sooner than a girl of the same age moving among the general population." Tuberculosis was responsible for 63 per cent of the total deaths among these nursing nuns. This appalling mortality is un-

derstandable if one remembers that Cornet's survey covered the period from 1864 to 1889, most of which was prior to the discovery of Koch's bacillus and even to the Pasteur era.

This warning stirred no response until 1910, when Hamel,² at the suggestion of Koch, inquired from 549 German institutions admitting tuberculous patients as to the morbidity from tuberculosis among their personnel. The survey included 2861 physicians and 14,140 nurses for the years 1906 to 1910. The rate of infection among them was found to be practically the same as that among the general population. This was in direct contradiction of Cornet's report.

Dublin,³ commenting on these figures, pointed out that the factors of age and duration of employment were not taken into account and that the reluctance of some of the nuns to submit to examination let a good many cases go unrecognized. Hamel's findings were, nevertheless, a long way from those of Cornet, and Dublin considered himself justified to conclude:

In view of the German figures and the personal experience of those who have long carried on America's tuberculosis work, more and more physicians and nurses should find themselves ready to enter this field of social service without the fears, usually present, of possible infection. With proper precautions taken, adults can engage in this work with well nigh perfect immunity.

The "proper precautions, up to the last few years, meant the hygienic disposal of the sputum. Recent events lead one to believe that this has been inadequate.

Dublin based his opinion on no less an authority than Trudeau, who wrote in a personal letter:

In the early days of the sanatorium, and for the past ten years, many of our employees, dining room maids and so forth were, as far as I know, healthy people. To my knowledge, none of these ever developed tuberculosis at the sanatorium.

*Read before the Worcester District Medical Society, October 9, 1940.
†Assistant superintendent, Rutland State Sanatorium.

The most authoritative American teachers and writers on the subject were then voicing a similar opinion. "Infection almost never occurs in sanatoria where the proper precautions are taken," Pottenger³ stated in the 1908 edition of his book. That the same opinion was prevalent in England, Germany and the United States is implied by what he added:

Although the Brompton Hospital, London, has treated more than 15,000 cases of tuberculosis during the past twenty years, yet, neither a nurse, a physician nor an attendant has become infected. The same record has been made in Falkenstein and Goerbersdorf, Germany, and in the Adirondack Cottage Sanatorium and Winyah in the United States. Here we have intimate association of patients and attendants for months and years with no infection occurring. We can safely say, then, that tuberculosis is only communicable when proper care is not used.

In 1917 he⁴ expressed the same belief:

The attendants of these institutions [sanatoriums and tuberculosis hospitals] instead of being prone to infection, seem to show even a smaller number of infections than occur in human beings generally.

Fishberg⁵ goes farther in the same direction. He quotes numerous French and German authorities, among them Saugman, who claims, "It is not dangerous for healthy adults to be coughed at by patients suffering from pulmonary or laryngeal tuberculosis." "During the thirty years of the existence of the Montefiore Hospital," writes Fishberg, "no nurse, orderly or physician has been observed to have been infected while attending to the needs of the tuberculous patients." He concludes, "Such facts have been quoted to disprove the transmissibility of tuberculosis, but in the light of our present knowledge, they merely prove that reinfection is impossible."

In 1924, Clark⁶ answered his own question, "Is caring for tuberculosis patients dangerous to the nurse?" by relating the experience of Aufrecht, who was unable to find a single case of infection among 263 nurses at the Madgeburg-Alstadt Hospital, where 3828 tuberculous patients had been admitted during the period 1880 to 1897, and that of Brunon, who studied the records of the Rouen hospitals for thirty years and found that nurses and attendants died of tuberculosis less often than the general population of that city.

In 1931, Fishberg⁷ endeavored to refute an article of Myers,⁸ and claimed to "know of no evidence that the incidence of tuberculosis in medical students is higher than that of other young men and women." In 1940, Brahdy⁹ concluded an article with the statement that: "The incidence of tuberculosis among hospital personnel is about the same as that in any similar group." He

makes an exception for nurses, whose higher rate of infection he attributes to their being tuberculin negative on entrance to the hospital.

The preceding quotations explain the impression prevailing among a good many to this day that a contact such as that of nurse to patient carries no danger of infection from tuberculosis.

From 1925 on, however, a decided change appeared in the figures and in the tone of the articles on this subject. Britton and Bollman¹⁰ and Shipman and Davis,¹¹ in this country, and Kirchner¹² and Mücke¹³ in Germany found the incidence of tuberculosis to be much higher among nurses than in the same age group in the community. Heimbeck,¹⁴ of the Oslo General Hospital, claimed in 1928 that 50 nurses out of 420, that is, almost 1 out of 8, developed tuberculosis in the course of their training. Reports of high morbidity rates from tuberculosis among interns, nurses and orderlies poured in from everywhere: 4.5 per cent, according to Fisher,¹⁵ of California; 29.1 per cent for one class of nurses at the Macon County Sanatorium, Illinois¹⁶; and 3 per cent in the New Zealand base hospitals.¹⁷ Geer¹⁸ found from 4.5 to 5.5 per cent at the Ancker Hospital, St. Paul, Minnesota, and Hedvall¹⁹ 5.3 per cent in probationary nurses at the Lund University Hospital in Sweden. Boynton²⁰ declared in 1939:

The tuberculosis infection rate is a hundred times greater in the student nurses on a general hospital service than in the students of the College of Education and five hundred times greater in student nurses on a special tuberculosis service than in the College of Education students.

Her study was carried out at the University of Minnesota Hospital.

Cases of infection of medical students have also come to the attention of epidemiologists. A wealth of material has been accumulated in various medical schools, in this country and abroad, showing that the rate of morbidity from tuberculosis among the second, third and fourth year medical students is generally greater than that among other young men and women of the same age group. Myers's²¹ first conclusion in an article written in 1933 was, "The incidence of tuberculosis among students and recent graduates of schools of nursing and medicine is so high that the disease may be looked upon as a serious menace to professional health workers." In 1939, Soper and Amberson²² surveyed the literature and gave their own figures in a comprehensive report. They noted an incidence of tuberculosis of 5.8 per cent among the medical students at the University of Pennsylvania in 1935-1936, decreasing gradually to 3.7 per cent in 1937-1938. Dr. Heath, of Harvard Medical School, wrote to Dr. Soper in 1938, "There

is no doubt that tuberculosis is the most important organic medical problem in the medical school." According to Soper and Amberson, however, Stanford University had only 1.0 per cent, Johns Hopkins 1.4 per cent, Yale a little more than 1 per cent and Columbia 0.4 per cent.

The incidence is higher abroad: Scheel²³ gives 23 per cent for the Oslo Medical School. The most recent and at the same time one of the most interesting reports comes from Lund University, Sweden, where Hedvall¹⁰ gives the figures listed in Table 1. This rate of infection

TABLE 1. *Incidence of Tuberculosis in the Different Faculties.*

FACULTY	NO. OF PERSONS EXAMINED	NO. OF CASES OF TUBERCULOSIS FOUND	TUBERCULOSIS IN DIFFERENT GROUPS	
			%	
Medical students	638	72	11	3
Philosophy students	1367	17	1	2
Theology students	409	12	2	9
Law students	488	9	1	8
Probationary nurses	434	23	5	3

among medical students is about the highest officially reported. The most enlightening part of Hedvall's report is the tracing of the main source of infection to the autopsy room. Samples from towels, trays and tables taken twenty-four hours after a necropsy examination contained tubercle bacilli on cultures, in spite of all precautions during the post-mortem procedure.

That the danger of contamination from this source may be serious is demonstrated by the following data obtained from various hospitals in Massachusetts. In 3766 post-mortem examinations at the Boston City Hospital in the years 1935-1939 inclusive, tuberculosis was found to be the primary or contributory cause of death in 285 cases, that is, at the rate of 7 per cent. Fourteen out of 236 cases, or 6 per cent, were reported from the Worcester State Hospital for 1937 and 1938. In the same years the Worcester Hahnemann Hospital had 3.8 per cent, the Worcester Memorial Hospital (Worcester) 2.7 per cent and St. Vincent Hospital (Worcester) 1.5 per cent. From the Worcester City Hospital comes the surprisingly low figure of 0.9 per cent for the years 1934-1938 inclusive. At the Buffalo General Hospital and Children's Hospital, Terplan²⁴ reported that the incidence of tuberculous lesions at autopsy of about 700 children and young adults was 5.9 per cent in those younger than seven years of age and 19.4 per cent in those between seven and eighteen.

The percentage of tuberculous foci found in the autopsy room of general hospitals indicates that there may be more lesions in their wards than one would suspect. Badger and Spink²⁵ noted

an annual average of 634 tuberculous patients admitted to the general wards of the Boston City Hospital from 1930 to 1934 inclusive. Ten per cent of the deaths from tuberculosis occurred in the general hospitals of upstate New York in 1936-1937,²⁶ and 20 per cent in the general hospitals of Massachusetts in 1939. Of 65,000 deaths from tuberculosis in the United States in 1933-1934, 5306 (7 per cent) occurred in tuberculosis departments of general hospitals.²⁷ In a recent x-ray survey of 4853 patients admitted at fifteen representative general hospitals, Plunkett and Mikol²⁸ found 2.6 per cent with pulmonary tuberculosis. This explains some seemingly paradoxical reports of higher incidence of tuberculosis among general-hospital nurses than among nurses at tuberculosis sanatoriums. There is less contact in the former institutions, no doubt, but that contact becomes more dangerous because it is unrecognized and because no precautions are taken.

EXPERIENCE AND EXPERIMENTS

My observations have paralleled the experience of those who have noted a high morbidity rate among their nursing personnel. From 1926 to 1936 inclusive, out of 174 healthy pupil nurses on admission to training, 16 developed tuberculous lesions demonstrable by x-ray, a morbidity rate of 9.2 per cent. They were all between the ages of eighteen and twenty-one. Of the 11 that were skin tested by the Mantoux method, 6 reacted positively, and 5 negatively. Four developed pleural effusions that cleared up spontaneously. Twelve showed parenchymatous lesions, but 8 of these never went beyond the minimal stage. Six had positive sputum. Fourteen took rest treatment for some time, varying between a few months to a year. Two refused to do so. Six received pneumothorax and one a phrenicectomy. Fourteen are now well. One is ill. One, who had been in contact with a tuberculous brother before entering the school, died. Three of the 16 nurses became ill from two to five years after they had left Rutland, and so far as they are concerned, the training school might well plead not guilty if it wished to do so. This would bring the morbidity rate down to 7.5 per cent.

To prevent further contagion, I have tried to determine the likeliest points of contamination in the immediate surroundings of the patients. The sputum is collected in a thick, oilpaper container and burned. This presents no difficulty. The droplets projected during coughing spells constitute the main problem. In spite of repeated instructions, some patients, because of thoughtlessness, neglect or lack of strength, fail to cover their mouths. Particles of sputum and saliva float

in the air for a short while and fall on the bed-covers, on the pillows and on the bedside tables, and may even reach the wall next to the bed. Other patients cover their mouths with their hands and contaminate the objects that they handle. One may easily judge from this that the dangers of infection vary greatly according to the habits and to the degree of illness of each person.

Cultures of tubercle bacilli were grown from the sterile water used to wash the bed sheets, the table, the walls and the floor of a room in which a particularly untidy patient had died the day before. The same procedure, repeated after the ordinary routine cleaning, — washing of walls, woodwork, floors, bedstead, table and chairs with soap and water, — still gave a positive result from the wall wash, but a negative one from the table and the floor washes. The experiment was carried out in several other rooms, with negative results. The sediment obtained from three floor sweepings in another room infected a guinea pig. No organisms grew from doorknob washes and from a basin of water kept on the bedside table of a very ill patient for twenty-four hours. No tubercle bacilli could be recovered from nose swabs of nurses returning from duty in the sickrooms or from the sterile water in which their masks had been left to soak after use.

The small scale on which these experiments were carried out detracts in no way from their value. They prove that tubercle bacilli are present in the immediate vicinity of tuberculous patients, and that their number increases with the stage of the disease, the severity of the cough and the lack of precaution taken by the patient.

DISCUSSION

The belief of the oldest observers, Valsalva, Morgagni, Laënnec and Villemain, after being partially disregarded by the medical writers of the early nineteenth century, has thus been exhumed and established on a solid foundation of facts and figures during the last ten or twelve years. The reason lies in the fact that the period from 1925 to 1940 has been illuminated by the light of the x-ray. There is no doubt that the morbidity from tuberculosis was probably as high in the twenty-five preceding years, but it could not be recognized clinically in time to be associated with the source of infection. The invasion of the lungs by the bacillus took place silently, without outward manifestations, or under the disguise of colds, gripes, influenzas and so forth, as it often does even today. It receded spontaneously in many cases or smoldered during the years of training to flare up later when the nurses had left the hospital and had been lost to sight.

Skin testing has been an even more sensitive gauge than the x-rays to determine the rate of infection in nurses and students. Of 126 nurses tuberculin tested at the Boston City Hospital, 60 per cent were positive on entering the school, and 90 per cent after their three years of training.²⁹ Of 70 student nurses negative to tuberculin at the beginning of their training, all but 10 were positive at the end, according to Amberson and Riggins.³⁰ Most of the reports show similar figures.

It is also possible that the increase in the incidence of tuberculosis noted during the last decade may be due, in part, to the enormous amount of study required from student nurses. Added to the work, the weight of this adverse factor may be sufficient to tip against them the sensitive scale in which their acquired resistance would otherwise counterbalance repeated exposures.

Much has been said and written on the question of allergy, and much confusion has resulted. On one point, most observers agree. The number of lesions recognizable by x-ray study and the number of clinical infections are far greater among the tuberculin-negative reactors than among the positive ones. This led some European and Canadian clinicians to immunize the former group by means of BCG. Among others, Heimbeck's³¹ statistics point to a remarkable degree of protection resulting from the use of this vaccine.

CONCLUSIONS

It seems generally accepted that the danger of contracting tuberculosis constitutes a serious hazard for young persons entering training school, and to a lesser degree, for medical students. This being so, the logical move is toward prophylaxis, and the following preventive measures are suggested:

No nurse, orderly or wardmaid should be permitted to work in a sanatorium before the age of twenty-one.

The affiliation of nurses to sanatoriums from general hospitals should be postponed to the third year of training.

The diet should be sufficient and well balanced. The work should not be too hard nor the hours too long. The living quarters should be spacious and well aerated. A false economy has often inspired shortsighted policies in regard to the three preceding items. The compulsory eight-hour day in state hospitals is commendable. A month's vacation a year is desirable.

All nurses should be skin tested, x-rayed, weighed and examined on admission and every four to six months during their training.

Vaccination of the tuberculin-negative reac-

tors by means of BCG is current practice in many European hospitals, and it seems to offer considerable protection. Medical opinion in this country is not yet prepared for the adoption of this protective measure.

Nurses should wear gauze masks of sufficient thickness while taking care of patients with open tuberculosis, especially while making beds and giving baths. They should be instructed not to shake the blankets, pillow-cases, bathrobes and so forth. They should be careful to wash their hands as soon as they are through with one patient, and to change their uniforms before leaving the ward. The soiled linen should be collected in bags and sent immediately to the laundry. The bags should be emptied directly into the washer with as little handling as possible.

All dishes, trays, glasses and so forth should be sent to the central dishwasher and sterilized by live steam. (Recent advances in the utilization of ultraviolet rays offer hope for their practical application in the field of hospital disinfection.)

Patients must be instructed not to cover their mouths with their hands, when coughing, but with paper napkins, which are thrown into paper bags pinned to the bedside tables.

In general hospitals, an effort should be made to detect patients suffering from pulmonary tuberculosis. If the cost of a routine chest film is considered too high, that of a fluoroscopic examination is negligible. The efficiency of the screen does not equal that of the film, but it is 80 per cent better than that of the stethoscope and 100 per cent better than no chest examination.

Where these or similar measures have been enforced, the rate of infection among nurses and hospital personnel has been brought below that of the general population.

HEMATOMA OF THE BRAIN*

PAUL J. BUCKLEY, M.D.,† AND JOHN McDOWELL MCKINNEY, M.D.‡

NEW YORK CITY

THE formation of a large localized hematoma within the substance of the brain is rather uncommon. The term, "hematoma of the brain," is used so that the pathologic condition under discussion may be strictly limited to large circumscribed collections of extravasated blood that are completely within the brain substance. Petechial or very small hemorrhages, massive cerebral hemorrhages rupturing into the ventricles or subarachnoid space and all circumscribed hematomas secondary to brain neoplasm are excluded from consideration. The fact that most hematomas of the brain produce signs and symptoms resembling the syndrome of an expanding intracranial neoplasm and that many of them respond well to surgical treatment is, perhaps, not generally appreciated. Comparatively few reports of such lesions that have been operated on can be found in the literature.

Four cases of hematoma of the brain have been collected from the records of the Neurological Institute during the last fifteen years, and in all cases surgical treatment was successful. In every case the hematoma was intracerebral and the preoperative diagnosis was either neoplasm or abscess.

CASE REPORTS

CASE 1. (N.I. 11910) N.M., a 59-year-old man, was admitted to the Neurological Institute on March 21, 1932, complaining of speech difficulty, occasional frontal headache and slight vertigo. The onset of his illness was 1 month before admission. In the evening, while playing cards and without any warning, he suddenly became unable to speak or to call names, and reeled on attempting to walk. The next day he was confused and spoke in a jargon, but at no time was he unconscious. He vomited on this day. He was admitted to a hospital, where an operation "through his nose" revealed pus. Two or three months prior to admission, he had noticed a momentary aphasia; he could not call the names of the stations while working as a subway guard. His son said that he had noted this difficulty in calling names about two years previously. He had never had a convulsion.

The patient was a well-built, vigorous man with a blood pressure of 160/90. There was a moderate arteriosclerosis, the heart was slightly enlarged, and the sounds were somewhat indistinct. There were a few transitory rales and a slight emphysema. The olfactory sense was poor on both sides. The optic disks were blurred, and there was a right homonymous hemianopia. The pupils were

sluggish to light. There was a right hyper-reflexia, and a nominal aphasia. The diagnosis on admission was a left-temporal-lobe neoplasm.

Examination of the blood revealed a red-cell count of 4,500,000 with a hemoglobin of 81 per cent, and a white-cell count of 9100, with a normal differential. The blood and spinal-fluid Wassermann reactions were negative, and the blood chemical findings normal. The first spinal fluid showed a + test for globulin, 75 mg. per 100 cc. total protein and 4 lymphocytes per cubic millimeter. Two subsequent fluids had negative globulin reactions; the total protein was 37 and 21 mg. per 100 cc., and lymphocytes numbered 18 and 2, respectively. The urine was normal. X-ray examination of the skull showed no disease; the pineal gland was not visualized. The various diagnoses considered were: left-temporal-lobe neoplasm; thrombosis of the left lenticulostriate artery; single acute hemorrhage of the brain (branch of the left mid-cerebral artery). Encephalography revealed a shift to the right of the lateral and third ventricles. The hippocampal recess was present on the right but absent on the left side, and the left temporal horn was only partially outlined. The findings were considered to indicate a left fronto-temporal tumor.

The patient was transferred to the surgical service, where a preoperative diagnosis of a left temporal meningioma was made. A left temporal osteoplastic flap was turned down by Dr. Byron Stookey. On the cortex of the temporal lobe was an area, about 5 cm. in diameter, that showed an increased vascularity. The upper gyrus of the temporal lobe, for a space of 2 or 3 cm., was almost canary yellow, whereas the surrounding gyri were quite white. A cannula was passed through the yellow degenerated area, and no fluid was found. On incision, a massive blood clot was found at a depth of 2 cm. Microscopic examination of the fresh tissue, including sections from the adjacent brain substance, was reported as "hemorrhage into degenerated tissue." The clot, which measured 2 by 3 by 2 cm., was removed, the edges of the cortex were allowed to come together, and the dura was closed. The pathological report showed that the tissue was composed of an edematous glial mat in which there were many compound granular cells containing hemosiderin, fat and masses of red cells. The diagnosis was: zone of reaction about an old cerebral hemorrhage.

The patient had a prompt recovery, and when he was discharged on May 10, 1932, aphasia was still present. The follow-up examination on August 2, 1933, showed that the aphasia persisted to a moderate degree. When he was last seen on August 2, 1934, two and a half years after operation, his condition was normal except for a mild nominal aphasia.

CASE 2. (N.I. 29949) L.P., a 15-year-old girl, was admitted to the Neurological Institute on August 23, 1936, complaining of headache, poor vision, nausea and vomiting. Two years before admission she had a generalized convulsion; previous to this she had frontal headaches and poor vision. Nine days before admission she began to have a left-sided headache, drowsiness, photophobia and nausea. The drowsiness increased, and the patient was

*From the Department of Neurology, College of Physicians and Surgeons, Columbia University, and the Neurological Institute, New York City.

†Assistant neurologist, Vanderbilt Clinic, New York City; attending neurologist, Holy Name Hospital, Teaneck, N. J.

‡Associate in neurology, Columbia University College of Physicians and Surgeons; associate attending neurologist, Neurological Institute of New York.

mitted in stupor. There was no history of trauma.

Examination revealed a well-nourished girl who was rosy and appeared acutely ill. There was a right lower facial weakness, the right abdominal reflexes were absent, and all the deep reflexes were absent except the right ankle jerk, which was increased. There was a right Babinski reaction. The fundi showed 1 to 2 diopters of papilledema on the right, and 4 to 5 diopters on the left. Pinprick was felt better on the left, and the patient moved the left extremities more freely than the right. The admission diagnosis was a left temporal neoplasm.

Examination of the blood showed a red cell count of 250,000 with a hemoglobin of 78 per cent, and a white cell count of 13,450 with 87 per cent polymorphonuclears. The blood Wassermann reaction was negative and the urine normal. X-ray studies of the skull showed that the middle meningeal channels were slightly larger than on the right.

On August 24, 1936, a left osteoplastic flap was turned by Dr. Fritz J. Cramer. Just under the tense dura a soft area was found in the center of the exposure. A needle was inserted to 4 cm., where a definite resistance was felt; the needle was forced deeper and about 25 cc of dark, bile-colored fluid was obtained. The dura was then opened widely. The exposed cortex showed wide, shallow gyri and a narrowing of the sulci, giving the impression of an underlying glioma. An incision was made in the posterior portion of the superior temporal gyrus to a depth of 3 cm. a large collection of old clotted blood was found. Several small, cystlike collections of clot were also found, and the impression was gained that the lesion was lobulated. A specimen was taken from the lesion and also from the yellow cortex. The surgeon stated that there were two hematomas, one about to rupture and one deeper and more solid. The pathological report was one old and one recent hemorrhage in the cerebrum.

The postoperative course was uneventful, and when the patient was discharged on September 5, 1936, she still had an unsteady gait and hyporeflexia.

In the summer of 1937, the patient had a recurrence of her original symptoms, but without any disturbance of consciousness. Repeated examinations disclosed only a slight increase of the deep reflexes on the right side and some suppression of associated movements on the right. Needle exploration in the region of the former hematoma showed no blood or fluid, and a ventriculogram revealed only slight evidence of a space-occupying lesion on the left. The patient slowly improved and left the hospital in good condition. She has been followed for three and one-half years, and there has been no essential change in her condition.

CASE 3 (NI 36399) A M., a 34-year-old woman was admitted to the Neurological Institute on January 4, 1938, in a semistuporose condition. She was found in this condition by her husband on December 29, 1937. She was unable to talk, but she could be aroused by stimulation. It was noted that she had a marked weakness of the right arm and leg. Her condition did not improve and after 4 days, she was sent to a hospital on the following day. She was admitted here. In 1923 she had been struck by a car; she was unconscious for 24 hours and was in bed for 4 months. A hysterectomy and an oophorectomy were performed in 1935. Not long after this, the patient became critical of those around her. She was untidy, irritable, and, at times, appeared dazed. In January, 1936, 2 years before admission, her husband found her in a semistupor; she was unable to walk or talk, but appeared to

be as well as usual on the following morning. In March, 1937, she was again found in the same condition, on recovery she complained of weakness of the right arm for several weeks.

Examination revealed a complete right hemiplegia, including the face, with all concomitant signs. The patient could not form words and understood very little that was said to her, but on repeated commands she could perform simple acts. Sensation was diminished on the right side. The right pupil was slightly larger than the left, but both pupils reacted to light and accommodation. The fundi showed a high degree of myopia and slight papilledema. The admission diagnosis was a left frontal neoplasm.

The blood count, urinalysis and blood Wassermann reaction were normal. The spinal fluid pressure was 420 mm. of water, the fluid was xanthochromic and contained 66 lymphocytes per cubic millimeter and 220 mg. of protein per 100 cc., and gave a +++ test for globulin. The gold sol curve was normal. X-ray examination of the skull showed moderate atrophy of the posterior clinoids and dorsum sellae.

On January 7, a ventriculogram showed evidence of a tumor in the left posterior frontal region. The patient was returned to the operating room, and a left frontoparietal flap was turned under local anesthesia by Dr. Byron Stookey. A large hematoma was found deep in the brain at the middle portion of the mid frontal and ascending frontal convolutions. The clot extended to a depth of 4 or 5 cm. and was surrounded by degenerated brain tissue. The pathological report of the tissue removed at operation was encephalomalacia and recent hemorrhage into the brain substance.

The patient gradually became brighter and tried to talk. She slowly regained the use of the right lower extremity. She was discharged on February 23, when she could walk quite well, but the right arm was still spastic and the aphasia was still present. Reexamination in February, 1940, showed an improvement in the aphasia; the patient could walk for a considerable distance. During the last two years, she has had occasional convulsions.

CASE 4 (NI 41189) H F., a 47-year-old man, was admitted to the Neurological Institute on February 28, 1939, with fever and delirium. Three weeks before admission the patient had a chill, with fever and aching muscles. On the next day he complained of severe headache over the left frontal area, he had a temperature of 101°F and a rapid pulse. Since then he had had a dull, left-sided headache, but after one week, he returned to work, although he was drowsy and depressed. On February 20, he was unusually drowsy and acted strangely. Instead of going to work, he confabulated with his wife and sneaked back to bed. In the afternoon he went to his club and borrowed \$50 for no good reason. While there he had his first visual complaint, he bumped into things, and he could not read. He had no diplopia but had marked dizziness, and he could not sign his check. After returning home he had projectile vomiting for the rest of the day and night. This was accompanied by a left-sided headache that soon became very severe.

On admission the patient was delirious, unco-operative and under heavy sedation, the temperature was 104°F. He had a pyknic habitus and was obese. The chest was normal. He was unable to walk, but had no demonstrable muscular weakness. The deep reflexes were hypotonic, and there was no Babinski reaction. Sensation was normal. The disks could not be seen well, the pupils reacted to light and accommodation; there was some

TABLE 1. *Summary of Cases Reported in the Literature.*

AUTHORITY	AGE	SEX	ETIOLOGIC FACTORS	INITIAL SYMPTOMS	CLINICAL COURSE	OPERATION	LOCATION OF HEMORRHAGE	OUTCOME
Cushing ⁴ (1933)	37							
	40	M	Trauma, high blood pressure	Unconsciousness	Thirty six hr later developed right hemiplegia, B P 300, P 50	Craniotomy and puncture	Left frontoparietal	Recovered, died later
Russell and Sargent ⁵ (1909)								
			Hypertension	Unconsciousness	Right hemiplegia and aphasia	Craniotomy	Left frontoparietal	Recovered
	42	M	Trauma	Unconsciousness (short)	Progressive to coma 24 hr later	Craniotomy and incision	Right temporal (large)	Recovered
	62	M	Trauma	Unconscious (10 hr)	Progressive to coma, 42 hr later had sudden hemiplegia	Craniotomy	Right temporal	Recovered
Bagley ⁶ (1932)	30	M	Trauma	Next day had headache	Gradual onset of intracranial pressure, 18 days later had hemianopia	Craniotomy	Right temporal (deep)	Recovered
	48	M	Arterio sclerosis	Focal convulsions (2 yr)	Gradual stupor and hemiparesis, aphasia and papilledema 16 days later	Craniotomy and incision	Left temporoparietal (extensive)	Died
	39	F	None	Sudden headache	Next day stupor, progressed to coma on 6th day, papilledema but no definite paralysis	Craniotomy and incision	Left frontoparietal (extensive)	Recovered, died 10 days later
	49	M	Syphilis?	Slowly became drowsy and confused	Gradual stupor, papilledema and sudden hemiparesis on 14th day, and worse on 20th day, B P 210/55	Craniotomy	Left temporal (too large to remove)	Died 24 hr later
	43	M	None	Sudden headache and confusion	Gradual progress, developed signs of left cortical lesion and hemianopia, worse on 12th day	Craniotomy and aspiration (30 cc)	Left frontal	Recovered
	35	M	None	Sudden hemiparesis, stupor	Progressive to coma and complete hemiplegia, critical on 12th day	Craniotomy and aspiration (40 cc)	Temporal	Second operation 5 mo later, recovery
	34	M	None	Sudden headache and hemiparesis	Gradual progress until on 19th day developed coma and complete hemiplegia	Right temporal decompression	No hematoma found (probably present)	Recovered
	14	M	Initial smoking	Vomiting	Unconscious soon, 5 days later had aphasia and right hemiplegia	Craniotomy and incision	Left temporal	Recovered
	40	F	Hypertension	Dizziness and diplopia	Soon had right hemianesthesia, hemiparesis and hemianopia, aphasia on 3rd day	Craniotomy and incision	Left occipital	Recovered, sudden death 6 mo later
de Luvereyns ⁴ (1934)	?	M	Trauma	Concussion and confusion	On 4th day had right hemiparesis and headache, increasing stupor, P 52 on 11th day	Craniotomy and evacuation (20 cc)	Left parietal	Recovered
	15	F	Trauma	Unconscious short time	Gradual paresis and anesthesia of left forearm, became critical on 14th day	Trephine and puncture	Right parietal	Recovered

(1933)

disassociation of the extraocular muscles, and nystagmus was present on lateral gaze. He was disorientated and had delusions. The blood pressure was 150/90. The admission diagnosis was a right frontotemporal brain abscess.

Blood examination showed a red-cell count of 3,740,000 with a hemoglobin of 60 per cent, and a white-cell count of 11,350 with 86 per cent polymorphonuclears; achromia, polychromatophilia and anisocytosis were present. Examination of the urine showed a ++ test for albumin, a + test for glucose and a + test for bile, with a few red and white cells per high-power field, and some granular casts. The spinal fluid was clear and had 8 white-blood cells and 5500 red-blood cells per cubic millimeter; the total protein was 68 mg. per 100 cc., and there was a + test for globulin. Culture of the fluid was negative. X-ray examination showed questionable atrophy of the posterior clinoids and dorsum sellae and changes that suggested early Paget's disease.

The patient was transferred to the surgical service, where it was thought that he had a right frontotemporal brain abscess. On the day of entry a right temporal decompression was done by Dr. Clement B. Masson. Following this operation, the patient's condition improved somewhat. On March 11, an encephalogram revealed a mass involving the right occipital and parietal lobes. A left homonymous hemianopia was found by the eye consultant. On March 14, a right parietotemporal flap was turned down by Dr. Masson. The cortex over the parieto-occipital region was rather soft, and there was a small, yellow discolored area in the posterior part of the operative field. This was incised, and a large hematoma, about the size of a lemon, was found at a depth of 3 cm. in the posterior part of the parietal and the greater part of the occipital lobes. Evacuation was done, and the patient made an uneventful recovery. Pathological examination showed encephalomalacia and hemorrhage in the cerebrum.

The patient was discharged on March 30, with a slight improvement in his visual fields, and was otherwise apparently well. He had no complaints, except occasional feelings of "nervousness," until June 15, when he became unconscious and was said to have a blood pressure "over 280." During the subsequent 6 months, he had 3 similar attacks, each of which lasted 15 minutes. He was readmitted on January 3, 1940, with a diagnosis of paroxysmal hypertension; the blood pressure was 205/140. A bilateral splanchnic resection was done in two stages. Following this, the patient improved greatly and the blood pressure dropped to 150/90 and remained at this level until he was discharged on February 10.

Heusner, in 1888, first reported an intracerebral hematoma successfully treated by trephination and puncture—the second case in the series collected by de Lauwereyns.¹ Since then a study of the literature has revealed 36 proved cases treated by surgery and 1 probable case that was relieved by trephination only, Kron and Mintz² reporting the only case of an intracerebellar hematoma. The greater number of these cases were reported after Naffziger and Jones's³ paper in 1928. Probably there are many unrecognized cases and some cases surgically treated but not reported. The essential points of the cases found in the literature are given in Table 1.

ETIOLOGY AND PATHOLOGY

With the exception of those cases in which the signs and symptoms follow soon after an injury, the causative factors often are not readily discernible. In 50 per cent of the cases there was a history of trauma to the head, usually of a considerable force, although in some cases the injury was slight and did not produce unconsciousness immediately. Some patients recovered from the initial symptoms, and a latent period, of varying extent, intervened before the development of the syndrome leading to surgery. When this latent period lasted from one to fifteen years, the relation of the previous trauma was not always clear.

TABLE 2. Etiologic Factors in All Cases.

FACTOR	No. of Cases
Trauma	22
Hypertension	4
Arteriosclerosis	2
Syphilis (doubtful)	1
Embolus	1
Otorrhea, prolonged	1
Coryza	2
Vomiting	1
None found	10

In 25 per cent of the cases no etiologic factor could be found; in the remaining 25 per cent vascular disease was present only six times. Two cases followed shortly after an upper respiratory infection. A summary of the etiologic factors is given in Table 2. Figure 1 shows that most cases—82 per

FIGURE 1. Age and Sex Incidence (2 cases omitted). The horizontally lined blocks represent males; the cross-hatched ones, females.

cent—occurred in men and were distributed throughout all the age groups, although none were found in the first decade. The location of the lesion is given in Table 3.

The post-traumatic hematomas are rather easily recognized, especially when the trauma produces symptoms that gradually progress to coma and when focal signs appear. Nevertheless, those that have a free interval and then a slow, progressive course are often mistaken for a neoplasm and in most cases cannot be differentiated by the most diligent investigations. The etiology of the so-called "spontaneous hematomas" is obscure, especially in those cases in which the onset is slow

TABLE 3. *Location of Hematoma in All Cases.*

and the progress is intermittent over a long period of time.

The mechanism of the fundamental pathologic process is obscure. Various authors have thought that simple fatty degeneration of the small arteries is an important factor in the development of spontaneous intracerebral hemorrhage in children. Bagley⁶ believed that spontaneous hemorrhage, either meningeal or intracerebral, was often due to the rupture of an aneurysm caused by arteriosclerosis, syphilis, trauma, infection or congenital defects. Craig and Adson⁸ have stated that the bleeding probably was due to venous rupture. Alexander and Putnam¹³ also think that venous thrombosis is an important factor in the development of many intracerebral hemorrhages. Many other authors¹⁴ have investigated intracerebral hemorrhage, but none have explained why some cases have a massive hemorrhage or an ordinary capsular stroke and why others result in hematoma formation.

The content of the hematoma varies according to the age of the lesion. In early cases there is almost unchanged blood or fresh clots, whereas the late lesions may be cystic and show, as Robinson¹² has stated, only gitter cells containing blood pigment adjacent to the capsule as evidence that the cyst originally was a hematoma. The development of a well-marked capsule, as described by Robinson and also by Douglas,¹⁶ is unusual; complete cicatrization of the hematoma has never been recorded, although multilocular cyst formation may occur. Usually there is only a glial and connective-tissue reaction in the brain substance surrounding the extravasated blood. In some cases there is laminated clot, which suggests recurrent bleeding.

DIAGNOSIS AND TREATMENT

As already mentioned, the majority of the intracerebral hematomas come to operation with the diagnosis of brain neoplasm, although the early post-traumatic cases are usually recognized. The time that may elapse between the trauma and operation is extremely variable (Fig. 2); the earliest

FIGURE 2. *Elapsed Time between Trauma and Surgery (2 cases omitted).*

operation was done eight hours after the injury, whereas the latest operation, in Case 3 of the group reported in this paper, did not take place until fifteen years after the trauma. The most favorable cases for operation seem to be those in which the development of the syndrome of increased intracranial pressure is gradual and accompanied by signs of a lesion implicating the more accessible areas of the brain. In these patients, the motor fibers in the internal capsule are involved by pressure from a distance and the resulting paralysis is not complete. However, it is possible that a certain number of slowly increasing massive intracerebral hemorrhages might respond favorably to aspiration before rupture takes place; such a case was cited by de Lauwereyns¹ and is included in Table I. It is interesting to mention that Craig and Lipscomb¹⁷ have reported a successful operation in a case of intraventricular hemorrhage due to a hemangioma in the wall of the lateral ventricle. Puech, Rappoport and Brun¹⁸ have described the removal of localized intraventricular hemorrhages. In some cases of intracerebral hematoma, single or repeated aspirations are sufficient for a cure; in others, incision of the cortex and evacuation of the fluid and clots are necessary. Encephalography or ventriculography may be required for accurate localization.

PROGNOSIS

There were 9 deaths in the group of 41 cases in which operation was performed, a mortality of 22 per cent. Two deaths were due to pneumonia on the tenth and fourteenth days after operation, and 1 resulted from a known pre-existing *Streptococcus viridans* infection. If these

deaths were excluded, the surgical mortality would be 15 per cent.

SUMMARY

Four cases of intracerebral hematoma are reported that were treated successfully by surgery. Thirty-seven other cases were found in the literature. Most of these cases responded well to surgical treatment.

HYPOTHYROIDISM IN INFANTS AND CHILDREN*

With Reference to the Ultimate Prognosis Concerning Intelligence and to the Withdrawal of Thyroid Therapy as a Diagnostic Measure

ROBERT P. GOODKIND, M.D.† AND HAROLD L. HIGGINS, M.D.‡

BOSTON

ALTHOUGH cretinism has for many years been known to result from deficiency of thyroid secretion, and although thyroid has had wide use in its treatment, an exact basis for a clear statement of the fate of treated cretins is still wanting. This is particularly true of eventual mental growth. The present study represents an attempt to secure more accurate information.

Lucas,¹ in 1927, presented the consensus when he said that treatment is usually followed by satisfactory physical results if begun early, although normal mentality is almost never attained; also, if the condition is recognized early, the continued administration of thyroid may produce a normal adult, but if treatment is delayed until the symptoms are so definite that the diagnosis is perfectly obvious, in most cases the child never gains actual normality.

Wieland² stated that results were less good in

so-called "early infantile" or congenital athyreosis than in acquired myxedema of children or adults; he pointed to hopeful cases that were diagnosed and treated soon enough, but in patients untreated for years he noted a poor response to treatment, particularly in intellectual development.

Fordyce,³ in 1933, after pointing out that the deficiency of thyroid may be of any degree, said that when careful treatment was begun in infancy and conscientiously continued, the ultimate prognosis was on the whole very good, although always uncertain. Some patients passed through childhood indistinguishable physically and mentally from normal children, and grew up into responsible citizens; others, however, responded only partially and became physically or mentally retarded, or both.

Holt and McIntosh,⁴ in 1936, stated, "We have not seen normal mental development, even in cases in which treatment was begun during the first year of life."

Rolleston,⁵ in 1934, emphasized that the earlier in life thyroid deficiency began, the less likely was well-marked benefit to result from thyroid therapy. Further, the earlier this treatment was started, the better were the prospects of success.

*From the Department of Pediatrics, Harvard Medical School, and the Massachusetts General Hospital

†During the years 1933 to 1936, Dr Goodkind made the observations included in this paper at the Harriet Lane Home, Baltimore, and the Massachusetts General Hospital. Dr Goodkind died on September 3, 1937, he had collected the data, but had not recorded an interpretation of the results. The tabulation, the conclusions and the preparation of the paper were completed by Dr Higgins

‡Assistant professor of pediatrics, Harvard Medical School, chief, Children's Medical Service, Massachusetts General Hospital

Observations have been made on 23 patients (13 from the Harriet Lane Home and 10 from the Children's Metabolism Clinic of the Massachusetts General Hospital) who had been under sustained treatment for thyroid deficiency—cretinism—for a period of five and a half to twenty four years.

The purpose of this study was to assemble data bearing on the ultimate prognosis of this group of patients with regard to mental capacity, especially as correlated with the age at the time of diagnosis and beginning of treatment, with the maintenance

Physical growth is indicated by height, which is recorded as "normal" when it was normal for age and family size, and as "under normal," when it was definitely subnormal.

The maintenance dose of thyroid is that which the patient was receiving at the time this series of observations was begun. It is recorded as desiccated thyroid gland USP (Armour or Parke, Davis), where Burroughs and Wellcome thyroid had been taken, 1 grain is calculated as equivalent to $\frac{1}{4}$ grain USP.

*After being without thyroid for 6 mo. basal metabolic rate -27 per cent. blood cholesterol level 242 mg. per 100 cc.

†5 x mo.

‡Seven mo.

§After being without thyroid for 12 wk. basal metabolic rate -29 per cent. blood cholesterol level 355 mg. per 100 cc. After 16 wk. -41 per cent. and 305 mg.

dose of thyroid (degree of functional deficiency of the patients' own thyroid glands), and with the presence or absence of normal growth. The therapy of many patients was omitted for eight weeks, basal metabolism and blood cholesterol determinations were made before and four and eight weeks after the medication was discontinued.

In selecting the patients, availability for study was the main criterion.

The results are recorded in Table I. Patients marked 'H' were seen at the Harriet Lane Home, those marked 'M' at the Massachusetts General Hospital.

The patients are listed in six groups according to their intelligence quotients, which were determined by Binet-Simon tests, fourteen years being regarded as the adult level. Thyroid therapy was being given at the time of the tests.

Basal metabolism and blood-cholesterol determinations were made at the time the patient was receiving the usual dose of thyroid and four and eight weeks after treatment had been discontinued. The few cases in which the data cover longer periods are indicated by footnotes.

The age at which diagnosis was made and treatment begun is given in years. The diagnosis was made before the patient was one year old in 9 cases, and under two years in another case. Analysis of these histories indicates congenital thyroid deficiency (cretinism).

The diagnosis in the other 13 cases was made later, the patients being two years of age or over. One of these patients, Case 23, showed symptoms of hypothyroidism at six months of age, the diagnosis was not made and treatment was not begun until two years later (congenital hypothyroidism).

with delayed treatment). Another patient (Case 6) was apparently normal—walking and saying words—at sixteen months of age; he had his first teeth at nine months. His symptoms began at four years of age, when growth stopped and lassitude and myxedema appeared; this patient had acquired myxedema and was not a congenital cretin.

The classification of the other eleven cases is more difficult. They are Cases 2, 3, 5, 8, 9, 11, 12, 13, 16, 17 and 18, and were recognized as cases of hypothyroidism relatively late. It is certain that the symptoms were not marked in the first year and a half of life; but there is information in the histories of each that makes one believe that the patients were then below par mentally and physically; as for instance delayed dentition or failure to stand, walk or say words at the normal age. An analysis shows that some congenital deficiency existed, but also that some thyroid function may have been present that later was lost.

Whether one is dealing at birth with true athyreosis, with partial thyroid deficiency or with normal thyroid function with loss of some or all function within the first two years of life, is always difficult to determine.

This differentiation of complete cretinism, partial cretinism, infantile myxedema and juvenile myxedema is hard to make because hypothyroidism has a gradual and insidious onset, because maternal hormone, absorbed by the child in utero, affords protection from symptoms for a considerable time, because minor amounts of hormone may be obtained from milk and food, because the patient himself cannot give a history pertinent to the diagnosis, and because wishful thinking on the part of many parents obscures deficiencies in their infants. Therefore, it has seemed best to group all the cases in one table.

Six patients showed a normal intelligence quotient, four being above 100. This does not agree with the usual impression that normal mentality in a cretin is never found. However, 6 patients were of low normal intelligence, and 11 were retarded. The mean mental level is marked by an intelligence quotient of 72.

Clinically, some cretins reach normal physical development under treatment, whereas others remain dwarfed to a greater or less degree. Of our group, 12 were definitely under normal height. The mean intelligence quotient of those of normal height was 85, and of the dwarfed group 68. Although the mental level tended to be higher in patients of normal height, in several cases of normal mentality the physical response to glandular therapy was subnormal.

Experience at the Children's Metabolism Clinic of the Massachusetts General Hospital has in-

dicated that the daily dose of thyroid U.S.P. (Armour) necessary to maintain normal metabolic function in completely athyreotic children is $\frac{1}{4}$ gr. per year of life up to six years of age; $1\frac{1}{2}$ gr. is sufficient for older children and adults.⁶ In practice, however, the daily dose is based on the clinical reaction as well as on the basal metabolism of the individual patient; some patients do better with larger doses, and others, especially the mentally retarded, do not react well socially on the dose necessary for maintenance of normal basal metabolism, and should accordingly receive less.

Examination of the data from the patients in our study seems to confirm the general thesis that the $1\frac{1}{2}$ -gr. dose for athyreotic patients is sufficient to maintain normal metabolism, and also a normal blood-cholesterol level. Only Cases 18, 20 and possibly 23 indicated a slightly higher need for thyroid; on the other hand, Cases 2, 11, 13 and 19 were receiving larger doses than $1\frac{1}{2}$ gr., but also had high metabolism or hypocholesterolemia or both.

Of the 6 patients with normal intelligence, 3 required full dosage of thyroid (Cases 1, 2 and 6), and 1 probably full dosage (Case 3), whereas 2 did not require full dosage for normal metabolism (Cases 4 and 5). In the group with low normal intelligence, full dosage was required in 2 (Cases 9 and 11), probably full dosage in 1 (Case 8), and less than normal dosage in 3 (Cases 7, 10 and 12). The respective figures for the retarded group were 7 (Cases 13, 15, 18, 19, 20, 21 and 23), 0, and 4 (Cases 14, 16, 17 and 22). Thus the percentages of complete athyreotic patients in each group were essentially the same: 66, 50 and 64.

The conclusion seems justified that the dosage of thyroid needed to obtain normal metabolism was not a factor in the ultimate mental capacity of the patient when under treatment.

Of the 11 cretins diagnosed and treated early, 6 received full dosages of thyroid and 5 did not require full dosage. Of the 12 cases diagnosed later, 6 required full dosage, 2 probably full dosage, and 4 only part dosage. The time of diagnosis and beginning of treatment did not determine the dosage needed later.

The age at which diagnosis was made and treatment started was also by no means the deciding factor in the ultimate mental capacity. In fact, the cases diagnosed as cretins and receiving first treatment early tended to be in the mentally retarded group; whereas only 2 cases among the patients with normal mentality were diagnosed before one year of age, there were 6 among the mentally retarded group. The diagnosis in Case 4 was made early because an older sibling had been a cretin.

Interpretation of these findings is difficult be-

cause we doubtless are dealing with different degrees of early thyroid function. Certainly mental retardation, if present, may lead to earlier recognition by parents and the physician that the child is abnormal.

Since the physical dwarfism, the maintenance dose of thyroid, and the age when treatment began are not clear-cut factors causing mental incapacity in hypothyroidism of children, the mental retarda-

elsewhere and placed on thyroid therapy; later, the question of whether the diagnosis was correct arises, and withdrawal of therapy is usually the only sure way to establish the diagnosis.

In 22 of our 23 patients, this was done; in 21, determinations of basal metabolism or blood cholesterol or both were made after four weeks and again after eight weeks, and in 2 cases also at longer intervals. In most of the patients, the lab-

FIGURE 1.

tion may quite well have the same etiologic cause as the athyria in certain cases, and the athyria may not be the cause of the mental retardation. The athyria would thus be looked on as causing mental slowing and not mental incapacity.

It has been the practice at the Massachusetts General Hospital to photograph each untreated cretin; this is a valuable procedure, since the signs and symptoms of cretinism disappear within a few weeks after treatment with thyroid is begun; a later review of the case for diagnosis is thus made more satisfactory. It frequently happens that a patient has been diagnosed as hypothyroid

oratory tests as well as clinical observations had proved the diagnosis of hypothyroidism after four weeks, and in all after eight weeks. One patient (Case 17) was apparently no longer suffering from hypothyroidism at the time of the study; after seven months without thyroid therapy the basal metabolism and blood cholesterol level were normal, although three years previously the metabolism had dropped from +10 to -21 per cent after fifty six days' withdrawal of therapy. This patient offers an exception to the statement, "Once a cretin, always a cretin."

The blood cholesterol level as an index of the

state of thyroid sufficiency has been quite well established both for hyperthyroidism and hypothyroidism. Hurxthal⁷ found that the hypercholesterolemia of hypothyroidism is marked and consistent and concluded that in the absence of a few other common causes, it indicated thyroid deficiency more specifically than the finding of a low basal metabolic rate.

Having at hand fifty-six parallel determinations of the blood-cholesterol level and the basal metabolism of cretins aged eight to twenty-five years, both when receiving and not receiving thyroid, we considered it desirable to try to correlate these findings. This has been done in Figure 1.

The correlation of the logarithm of the blood cholesterol value, in milligrams per cent, with the basal metabolic rate, in terms of percentage deviation from normal, shows that a significant relation exists and that the equation,

$$\text{Log. (cholesterol)} - 2.32 = -0.0148 (\text{B.M.R.} + 7.4),$$

will allow the prediction of the cholesterol with an error of about 17 per cent, or .07 in terms of logarithms.*

Analysis of our data confirms the findings that cholesterol determinations of the blood serum or plasma are a good index of the degree of hypothyroidism and correlate well with the metabolic rate determinations. The method of choice in evaluating treatment apparently depends on the availability and ease of the two laboratory procedures. The low cholesterol findings before treatment in Cases 13 and 19 suggest that 3 gr. of thyroid was too big a dose; the findings in Cases 11 and 21 are similarly suggestive.

SUMMARY

Observations were made on 23 hypothyroid patients under treatment from five and a half to twenty-four years, all but one, so far as can be ascertained, being not wholly normal during the first year of life, and therefore probably congenital cretins.

*We are indebted to Professor E. B. Wilson, of the Harvard School of Public Health, for this statistical analysis.

Six showed intelligence quotients between 90 and 112, 6 between 70 and 89, and 10 below 70.

Although the mean intelligence quotient was higher in the patients of normal physical growth than in the dwarfed, 2 of the dwarfed group had normal intelligence and many of normal size were mentally retarded.

The age of diagnosis and beginning of treatment was usually earlier in the ultimately mentally retarded cases than in those of normal intelligence.

The criterion that $1\frac{1}{2}$ gr. of thyroid U.S.P. daily will raise to normal the basal metabolism of the athyreotic patient over six years of age was confirmed.

The degree of thyroid deficiency, as measured by the amount of thyroid necessary to maintain normal metabolism, was not proportional to the degree of mental retardation.

The cholesterol content in blood serum or plasma showed close correlation with the basal metabolic rate.

Since the ultimate mental capacity of the hypothyroid child under adequate treatment was not strictly related to physical growth, to delay in beginning treatment or to the dose of thyroid necessary for normal metabolism, the cerebral deficiency can probably be regarded as congenital and from the same cause as the thyroid damage.

Determinations of the basal metabolic rate and the blood-cholesterol level following the withdrawal of thyroid therapy are of diagnostic significance in the doubtful cases of treated cretinism.

ACUTE LARYNGEAL OBSTRUCTION AS A COMPLICATION OF MEASLES

H. H. SHUMAN, M.D.*

FITCHBURG, MASSACHUSETTS

ACU TE laryngeal obstruction is a rare but serious complication of measles. Very few textbooks on the subject of pediatrics and communicable diseases mention this sequela, and a perusal of the literature reveals that little consideration is given to it.

Morse,¹ Barnhill,² Coakley³ and Scheppegegrell⁴ mention this complication in the discussion of measles, but they do so in a cursory manner, and say little or nothing concerning its management.

Homrighouse and McKee⁵ cite a case of a twenty-one-month-old boy who developed obstructive laryngeal symptoms on the tenth day of measles. The boy was anesthetized for the purpose of bronchoscopy, but died suddenly while under anesthesia.

Oliver and Turner⁶ described 3 cases of laryngeal obstruction that occurred during an epidemic of measles in Beirut, Syria, in 1933. Obstructive symptoms in all 3 cases developed during the height of the rash; all were treated by tracheotomy. Two of the children survived.

Neffson and Wishik⁷ discuss this subject in their classic paper on acute infectious croup. Their findings are most interesting because they present the largest series of cases—35 patients. Statistically, the condition of acute laryngeal obstruction occurred in less than 1 per cent of the total number of cases of measles (3677) admitted to the Willard Parker Hospital from June, 1931, to June, 1934. Contrary to most opinions, acute laryngeal obstruction can occur at any stage of measles—in the pre-eruptive, eruptive or post-eruptive stage. Pathologically, these cases showed the edema to be located chiefly in the supraglottic area, and usually present to a marked degree. Laryngeal cultures showed *Staphylococcus aureus* or *Streptococcus haemolyticus* as the offending agent in about equal proportions. About 50 per cent of the cases went on to develop pneumonia as a further complication.

In the experience of the authors mentioned above, treatment by intubation was not the method of choice, for in their hands 6 of the 7 patients treated by intubation died.

It is obvious, of course, that, for the relief of laryngeal obstruction, intubation is a far better procedure than tracheotomy from the point of

view of final result and comfort of the patient. If properly done and if the patient is carefully supervised while the tube is in the larynx, intubation causes fewer complications, is less devastating to the patient and esthetically is the procedure of choice.

The following 3 cases of acute laryngeal obstruction complicating measles have come to my attention in the last two years.

CASE REPORTS

CASE 1.[†] P. O. (No. 96619), a 2-year-old boy, sick for 4 days with measles, entered the South Department of the Boston City Hospital. For the few hours before entry he experienced rapid breathing, cyanosis and moderately deep suprasternal, substernal and intercostal retractions. The voice was hoarse, the breath sounds were somewhat diminished throughout, and there were many scattered moist rales in both lungs. The patient was placed in a croup tent and given steam inhalations, but his condition became progressively worse. He was laryngoscoped, a culture of the larynx was taken, and he was intubated by visual method that evening, a No. 1 tube being used. The culture showed a predominance of *Streptococcus haemolyticus*.

During the next 6 days he seemed comfortable with the tube in the larynx, but on the morning of the 7th day he coughed up the tube and his condition became immediately alarming. It was necessary to reintubate him within a few hours. This time a No. 2 was used. This was kept in place for 1 week. The patient improved markedly, and on the 7th day he was extubated by the visual method; he was discharged 2 days later in good physical condition, except for slight hoarseness.

CASE 2.[‡] W. O'C., a 4-year-old boy, was admitted to the Belmont Hospital, Worcester, Massachusetts, after a hurried 25-mile trip over the highway, in a precarious condition. He was markedly dyspneic and presented marked substernal retractions. There was a fading erythematous maculopapular rash, with marked injection of the conjunctivas, injection of the posterior pharynx and enlarged, boggy tonsils. Harsh breath sounds were heard in the upper part of the chest only. The larynx was not visualized, but on indirect intubation marked edema of the epiglottis was noted. A culture of the nose and throat showed *Staphylococcus aureus*. No laryngeal culture was attempted.

The patient was intubed immediately after admission by the indirect method, without apparent relief. He was therefore extubated, but the retractions became so severe that he was almost immediately reintubated, this time with good effect. He spontaneously extubated during the night of admission, and was again reintubed. During the next 4 days the patient's condition continued to improve. On the 5th day he again spontaneously extubated and had to be

[‡]By permission of Dr. Elizabeth Bishop, resident physician, Belmont Hospital.

reintubed once more. On the following day, he again coughed up the tube, but his condition seemed so improved that reintubation was not considered necessary. Convalescence from then on was uneventful, and he was discharged on the 14th day with no abnormal physical findings other than a slight huskiness of the voice.

CASE 3. R. O'C., a 4-year-old boy and a brother of W. O'C. (Case 2), entered the isolation unit of the Burbank Hospital on the 2nd day of a measles rash, because of a sudden and progressive respiratory difficulty, a moderate degree of cyanosis and a marked hoarseness of voice. He was extremely restless, and breathing involved marked infra-sternal and suprasternal retractions. He was placed in a croup tent and given steam inhalations, but the degree of obstructive symptoms became more marked. A throat culture taken at this time revealed rare gram-positive diplococci, occasional *Staph. aureus* and a short-chained streptococcus; no *Corynebacterium diphtheriae* were seen.

Laryngoscopy showed considerable swelling of the subglottic and supraglottic areas. A No. 3 tube was inserted into the larynx, with prompt relief of symptoms. One hour later in an attack of spasmodic coughing the tube came out, and was reinserted by the visual method. He was again relieved of obstructive symptoms and went to sleep. About 6 hours later he coughed up the tube, and this time a No. 4 tube was inserted. This tube fitted rather snugly. He kept this tube in and improved rapidly from that time on. On the 3rd day his temperature fell to normal, and the patient was extubated by the visual method. The symptoms did not return, and he was discharged on the 5th day in good physical condition.

CLINICAL NOTE

A NOTE ON PAIN AND ITS REFERENCE IN CASES OF RENAL INFARCTION

PAUL D. WHITE, M.D.,* AND
RENO R. PORTER, M.D.†

BOSTON

STIMULATED by a history of unusual reference of pain to the testicle as the result of renal infarction in Case 26231¹ of the "Case Records of the Massachusetts General Hospital," we have reviewed the symptomatology in one of the larger reported series of cases of infarct of the kidney proved at post-mortem examination, and in cases encountered at the Massachusetts General Hospital in the last seven years. In 1933, Barney and Mintz² reported an analysis of 143 cases of renal infarct from the autopsy records of the Massachusetts General Hospital. Of this series, 117, or 83 per cent, were on the medical wards. Almost all the patients on the medical services were found to have acute or chronic heart disease. Sixty-eight

SUMMARY

This paper calls attention to the infrequent but serious complication of acute laryngeal obstruction in measles. Three cases are presented that were treated by intubation. Characteristic of this type of management is the necessity for careful nursing supervision and frequent reintubation, but this is compensated for by the infrequent occurrence of complications and by the freedom from the danger of repeated blocking, which is always present when a tracheotomy tube is used. In addition, there is no scarring of the neck, a condition of benefit to the patient in later life.

per cent of the cases were afebrile. Nausea and vomiting were rare, being noted in only a little over 8 per cent. In 88 cases, or 65 per cent, there was no pain or tenderness at any time. Among the cases with pain and tenderness, none were associated with costovertebral tenderness, which has so often been associated with renal disease. There was no mention of the symptom of typical renal colic in any case.

Among 75 cases of renal infarction that came to autopsy at the Massachusetts General Hospital during the seven years from January 1, 1933, to January 1, 1940, 20 patients gave histories of recent or fairly recent abdominal pain. However, most of the cases were eliminated because of the location of the pain and because of its association with other complicating abdominal conditions, such as cholecystitis, cholelithiasis, dissecting aneurysms of the abdominal aorta, renal carcinoma, nephrolithiasis and mesenteric thrombosis. There remained 3 patients with histories typical of renal colic—severe pain in the sides of the abdomen or flanks, costovertebral tenderness, nausea and vomiting—in whom no other intra-abdominal condition existed to account for the symptoms. In 2 of these cases, the pain radiated down to the lower quadrants of the abdomen, but in no case was there radiation of the pain to the genitalia.

*Lecturer in medicine, Harvard Medical School; physician, Massachusetts General Hospital.

†Research fellow in medicine, Harvard Medical School; graduate assistant in medicine, Massachusetts General Hospital.

Other rare cases of renal colic and radiation of pain to the genitalia in renal infarction have been encountered, as noted by Aschner,³ who recorded 2 cases, by Falci,⁴ who cited 1 case (among 22 of renal infarction collected from the literature, in most of which there was flank or lumbar pain, with reference to the thigh in a few and with vomiting in a few), and by Loeb,⁵ who, in a discussion of diseases of the kidney, remarked that in renal infarction it was possible to have a clinical picture identical with that of renal colic.

It has been suggested by Ehrstrom⁶ that the pain in renal infarction is due to swelling of the kidney and consequent stretching of the capsule.

The pathogenesis of the striking renal colic in Case 26231, with unusual radiation of pain to the testicle, such as is characteristic of renal and ureteral calculus, can be adequately explained as the result of referred symptoms from the renal involvement alone, without the need of incriminating ureteral or bladder lesions. It is unlikely that a blood clot passing through the ureter would have caused the pain, because the pain came at once,

before the blood clot might have formed, and because there was very little actual blood in the urine.

It has been mentioned at times that the clinical picture of renal infarct can so simulate that of true renal colic that in rare cases such patients are operated on for the removal of the supposed stone. However, we were unable to find any such case in the autopsy and surgical pathological files of this hospital, and conversations with members of the urological staff failed to reveal any such case.

Thus, in renal infarction, pain is oftener absent than present, renal colic is very uncommon and radiation of pain to the genitalia is exceedingly rare.

MEDICAL PROGRESS

HEMATOLOGY*

WILLIAM DAMESHEK, MD†

BOSTON

INFECTIOUS MONONUCLEOSIS

SINCE cases formerly diagnosed as "grippe," influenza, septic sore throat, mesenteric adenitis, appendicitis, continued fever and so forth are being recognized as examples of infectious mononucleosis, the importance of this disease in general practice is gradually becoming more and more evident. That the disorder frequently, if not usually, goes unrecognized is by now a truism. If the practitioner were to examine carefully for enlarged lymph nodes and spleen in every case of fever, the percentage of recognized cases would be greatly increased. Too often, it seems, the throat, heart, lungs and abdomen are examined with very little attention to possible lymphadenopathy. If, furthermore, blood smears were made routinely, the disease would be recognized far more frequently. The blood picture is so characteristic, once it is known and recognized,

that it permits ready diagnosis. There is lymphocytosis (not monocytosis), the lymphocytes being of all possible sizes, shapes and staining characteristics. Great variability in the type of lymphocyte is the outstanding feature—quite the reverse of acute leukemia, in which a "monotonous" blood picture with one type of lymphocyte, usually the lymphoblast, predominates. There is furthermore no anemia, and hardly ever any reduction in blood platelets—again quite in contrast to acute leukemia, in which rapidly progressive anemia and thrombocytopenia are the rule. The introduction of the heterophil agglutination test has been of material aid in further defining these cases, which usually give a positive agglutination reaction with sheep's red blood cells.

There is almost no limit to the bizarre manifestations of the disease. As in all generalized conditions (polycythemia, metabolic disorders and so forth) peculiar localizations occasionally crop up. Jaundice, which looks typically like the catarrhal type, may be the presenting symptom. A case of this type, associated with a positive Wassermann

*From the Joseph H. Pratt Diagnostic Hospital and the Blood Clinic of the Boston Dispensary. Aided by a grant from the Chaulson Fund Tufts College Medical School.

†Assistant professor of medicine Tufts College Medical School was on phygia. Joseph H. Pratt Diagnostic Hospital chief of Blood-Vitamin Clinic, Boston Dispensary.

mann reaction, is reported by Fowler and Tidrick.¹ As these authors point out, "it is not improbable that many cases diagnosed as catarrhal jaundice have actually been infectious mononucleosis." Positive serologic tests for syphilis not infrequently occur concurrently with the positive heterophil reaction. Bernstein,² who gives a comprehensive review of the disease, found a transiently positive Wassermann reaction lasting for two or three weeks in 8 of 44 cases. On the other hand, Davidsohn,³ of Chicago, who has been responsible for some of the outstanding work with the heterophil reaction, has failed to find one case with positive serologic tests for syphilis in his carefully studied series. At any rate, changes in the serum may cause agglutination of sheep's red cells and positive Wassermann, Kahn and Hinton reactions. These changes are apparently not the result of the same serologic abnormality, but their mechanism is at present unknown.

Bernstein, in his review, cites such symptoms as edema of the eyelids, skin eruptions, and central-nervous-system manifestations, which are occasionally present. Templeton and Sutherland⁴ point out the frequency of an exanthem in the disease—17 of 91 cases. In 12 cases, the rash was practically indistinguishable from that of German measles. In this connection, it should be noted that the latter disease is associated with well-marked lymphadenopathy and not infrequently with an abnormal lymphocytic reaction in the blood; one wonders whether they might be related.

The etiology of the disease and the manner of its spread remain obscure. Epidemics are occasionally seen, but even in these, the type of spread has not been worked out. The pathology of the disorder has naturally not been extensively studied because of the absence of autopsied material. However, biopsied lymph nodes have resulted in an understanding of the fundamental nature of the lymphocytic proliferation. Gall and Stout,⁵ on the basis of ten biopsied lymph nodes, claim that there is a specific pathologic picture. This is characterized by marked proliferative activity of the pulp, extensive but focal proliferative activity of clasmacytes and the appearance of large numbers of specific so-called "infectious mononucleosis cells." These are large lymphocytes with abundant basophilic cytoplasm, which with phloxin and methylene blue stains have a filmy-blue quality of the cytoplasm.

The prognosis is always good. There is no specific therapy for the disease, which indeed usually requires only symptomatic treatment. The sulfonamide drugs are of no value unless there is a secondary infection with streptococci or pneumococci. Occasionally there is a rather marked, as-

sociated Vincent's infection, which may cause a severe cervical adenitis. If this is present, an injection of 0.3 gm. of neoarsphenamine intravenously may be of great benefit.

REACTIONS OF THE BLOOD TO DRUGS

The reactions of the blood cells to the sulfonamide group of drugs continue to be the subject of much comment. These drugs have an effect on hemoglobin that is usually slow but may occasionally be rapid (acute hemolytic anemia). In the slow type of response, methemoglobin and sulfhemoglobin, which are inactive pigments, are slowly formed, and are probably responsible, at least in part, for the cyanosis commonly noted. Earlier conflicting results regarding the presence or absence of these pigments have been resolved by greater accuracy of methods. Smith,⁶ experimenting with white rats, found that sulfanilamide given orally for a month caused small but significant amounts of methemoglobin and somewhat larger amounts of sulfhemoglobin. There was a definite reduction in hemoglobin. These results are borne out in human observations by Harris and Michel.⁷ The degree of methemoglobinemia was proportional to the sulfanilamide concentration. Vigness, Watson and Spink⁸ found that the cyanosis of sulfanilamide therapy could be explained by the presence of methemoglobin, rarely sulfhemoglobin, and that methylene blue abolished the cyanosis as well as the abnormality of hemoglobin pigment. Erf and MacLeod⁹ noted an increase in fecal urobilinogen output (increased blood breakdown) in cases of pneumonia treated with sulfapyridine. Three of 8 cases so treated developed a definite hemolytic anemia. Paul and Limarzi¹⁰ found that the bone marrow became more hyperplastic after sulfanilamide administration, again indicating a hemolytic effect. Spence and Roberts¹¹ report a case of extreme leukocytosis and acute hemolytic anemia with sulfanilamide administration. They point out that leukocytosis may be an early hidden manifestation of a hemolytic process associated with administration of the drug.

The subject of acetanilide poisoning has received scant attention in comparison with that of the toxic reactions of the sulfonamide drugs. However, Meulengracht and his collaborators¹² have very properly revived interest in the matter, especially since drugs such as Bromo-Seltzer are so commonly used in this country. As with sulfanilamide, acetanilide rapidly produces cyanosis, which for years has been thought to be due to methemoglobin or sulfhemoglobin. These authors found that the cyanosis was caused by the decomposition of acetanilide to dark-colored derivatives of

para amidophenol. Since continuous use of the drug is followed by "a peculiar and gray addiction" with persistent fatigue and headache, the authors recommend that prescriptions for the drug should not be refilled. In this country more stringent regulations might well be made.

IRON-DEFICIENCY ANEMIA (HYPOCHROMIC ANEMIA)

Chronic iron-deficiency anemia is usually the end result of a group of etiologic factors: a diet inadequate in iron, achlorhydria, malabsorption of iron-containing material from the bowel, hemorrhage (menorrhagia and hemorrhoids), multiple pregnancies and so forth. One factor alone is rarely at fault in these cases, although achlorhydria may be the crux of the problem. Thus cases with such abnormalities as impaired dietary and menorrhagia might develop very little anemia unless the gastric juice were also affected.

Iron-deficiency anemia in children is discussed by Abbott and Ahmann,¹³ who studied a group of 883 rural school children in Florida. Half of them were anemic (below 70 per cent hemoglobin, Dare), and a hemoglobin between 70 and 85 per cent was found in nearly one third. A number of children had been born of anemic mothers and had probably been anemic to some extent for the greater part of their lives. Pallor, general muscular weakness, lassitude and a faint systolic murmur were commonly present when the hemoglobin level was below 50 per cent. As etiologic factors are listed poverty, food high in carbohydrate, hookworm infestation and various gastrointestinal disturbances. It is also possible that certain infants born in families with either pernicious anemia or chronic hypochromic anemia may have a constitutionally defective gastric mucosa, which might result in failure adequately to digest organic iron-containing foods.

By the use of radioactive (so called "tagged") iron, Hahn and his co-workers¹⁴ at the University of Rochester have been actively engaged in the study of iron metabolism. In animals, it is possible to study the labeled iron from the time it enters the circulation until it is excreted. Its incorporation in the hemoglobin molecule has also been studied.¹⁵ In the dog with chronic iron deficiency, iron is rapidly taken up in the red blood cells, and the body cells are apparently avid for it, whereas the normal animal to a great extent rejects iron.

In the patient who has had a hemorrhage, as from a peptic ulcer, it has long been debated whether added iron was of value. Lyons and Brenner¹⁶ contribute to this discussion by an analysis of 237 cases of bleeding peptic ulcer. The rate

of erythropoiesis following hemorrhage appeared strictly dependent on the degree of anemia, and was "fully as good as that reported for patients treated with a liberal, 'purged diet' and iron." Transfusion itself appeared to have no effect on the rate of red cell production.

In pregnancy, the incidence of anemia is quite high, amounting, Bethell, Gardiner and MacKinnon¹⁷ state, to 54 per cent of 158 cases studied. The majority of these cases were of the iron-deficiency type. Since normal gestation places no great demand on maternal iron stores, the anemia was due mostly to other factors: low iron reserves, restricted utilization of reserve iron, impaired absorption of iron during gestation and low dietary intake of iron. It should be noted that poverty and an inadequate intake of food iron frequently go together, since the foods containing large amounts of iron are for the most part the most expensive (meat, liver, green vegetables and eggs). If inorganic ferrous preparations are given in cases of hypochromic anemia, there is an excellent response; the routine use of iron during pregnancy is thus a justifiable procedure.

In males, chronic hypochromic anemia is almost always due to persistent bleeding, particularly from the gastrointestinal tract. Given a case of apparently idiopathic hypochromic anemia in a male, the stools should be searched for occult blood, and gastrointestinal studies should be instituted. Not infrequently, herniation of the stomach is discovered. A number of such cases have been reported in recent years. Two have recently been reported by Dyke and Dyas.¹⁸ In the second case, occult blood in the feces was present, although the test was negative in the first case. A negative finding for occult blood does not necessarily rule out the possibility that the anemia is associated with the hernia, since persistent bleeding in the past may well have taken place.

Recently, the possibility that some types of vitamin deficiency might be linked with hypochromic, microcytic anemia has been discussed. Thus, in dogs, a deficiency in the "rat antidermatitis principle"—vitamin B₆ or pyridoxin—has been shown by Fouts, Helmer and Lepkovsky¹⁹ to result in hypochromic anemia, responding to pyridoxin administration. This has been confirmed by Borson and Mettier.²⁰ Whether these experimental observations have any relation to the hypochromic anemia of human beings is questionable.

Chlorosis which is usually considered as practically extinct, is probably far commoner than is generally appreciated. It is likely that many diagnoses of chlorosis prior to 1900 were made without benefit of careful laboratory examinations, and it is therefore possible that many cases of such con-

ditions as pulmonary tuberculosis, chronic hemorrhage and even neurasthenia were diagnosed as chlorosis. In taking histories in adult women with chronic iron-deficiency states associated with achlorhydria, it is noteworthy that the great majority have been "anemic for years" or "anemic since childhood" or were "treated with iron twenty years ago." In all probability, many of the cases of chronic idiopathic or primary hypochromic anemia of late adult life have been examples of "chlorosis" in youth. The central feature of both these disorders is probably the histamine achlorhydria, which may indeed be indicative of a constitutional gastric atrophy. It is possible that this abnormality may lead to certain cases of so-called "nutritional anemia" in infancy, to chlorosis in puberty, and to primary or idiopathic hypochromic anemia of late adult life. Certain cases may furthermore develop pernicious anemia as a late manifestation. The marked reduction in hemoglobin that ensues with chronic iron deficiency results in a disappearance of the normal healthy red color from the skin, with the result that the basic yellowish color of the skin becomes quite obvious. Owing to a common tendency in medicine to exaggerate colors, the yellowish coloration has been termed "green," possibly because greenish overtones may be seen by the more artistic observers. Thus, the so-called "green-sickness" or chlorosis is in all probability simply a chronic iron-deficiency state of young people, usually young women, and usually with an atrophied gastric mucosa. In my series, and in that of Olef,²¹ complete histamine achlorhydria was usually present. Response to inorganic iron is rapid, but relapses occur when the medication is discontinued, so that a maintenance dose is recommended.

PERNICIOUS ANEMIA

Pernicious anemia is a deficiency disease. As such, it may result from an inadequate diet, a lack of digestion of protein by an atrophied gastric mucosa, which fails to produce "intrinsic factor," malabsorption by the bowel, or hepatic disease (inadequate storage), or in pregnancy it may follow the loss of liver-extract substance to the fetus. More recently, the possibility of lack of utilization of liver-extract factor by the body (so-called "achrestic anemia") has been postulated. It should be noted that in a given case, a number of etiologic factors may operate together. Thus, both the diet and the intrinsic factor may be grossly deficient; if only one were deficient, the patient might not develop the deficiency state. Multiple factors are thus important, and it should also be noted that the resulting changes in the body are also multiple. Pernicious anemia is not only

an anemia; it is a generalized disturbance—a starvation of the body for liver-extract substance with the result that graying of the hair, glossitis, gastrointestinal manifestations and central-nervous-system disturbances result. The anemia is simply one aspect of the deficiency, resulting specifically from lack of liver-extract substance by the bone-marrow cells.

The constitutional nature of pernicious anemia is discussed in an article by Schemm,²² in which 5 authenticated cases in the same generation of one family were studied. In addition, 2 cases in each of five families were observed. It is probable that all the hereditary cases are based on an inherited gastric (or gastrointestinal) mucosal atrophy with resultant diminution or even complete lack of intrinsic factor. Schindler, Kirsner and Palmer²³ discuss gastroscopic observations in the disease. Histologically, atrophic gastritis is chiefly characterized by extreme thinness of the gastric mucosa due to disappearance of the gastric glands. Schindler and his co-workers believe that the various changes are the end result of chronic inflammation, although most observers believe they are degenerative. A certain parallelism between changes in the tongue, the mucosa of the stomach and the spinal cord is usually present, although occasionally the gastric mucosa may be atrophied without changes of these organs.

Achrestic (lack of utilization) anemia has been described for the third time by Israëls and Wilkinson.²⁴ In their first papers, these cases of apparently typical pernicious anemia presented two unusual features: free hydrochloric acid in the gastric juice and failure to respond to liver-extract therapy. Because potent liver-extract principle was present in the livers of some of these autopsied patients, it was postulated that this material could not be utilized by the body. In the most recent paper, the authors' concepts have apparently undergone some modification, for of the 6 cases reported the only abnormality was the presence of free hydrochloric acid in the gastric juice. A definite response, perhaps somewhat slower than usual, occurred in all cases following the use of liver or gastric extracts. The matter of intrinsic factor in the gastric juice was not studied, although it appears (according to Castle's well-known experiments) that this is of greater fundamental importance than the presence of free hydrochloric acid. I recently observed a case similar to those reported by Israëls and Wilkinson, since the two uncommon features noted by them were present, in addition to the ordinary characteristics of pernicious anemia. Only when large doses of Ventriculin were given did the patient begin rapidly to improve.

Sprue is probably another subtype of the larger pernicious anemia syndrome. Castle and his co-workers²⁵ considered that the two diseases were identical, and it cannot be doubted that histologically and hematologically they often cannot be differentiated. Rodriguez-Molina²⁶ found that although the bone-marrow and hematologic aspects of sprue were identical with pernicious anemia, other features served for differentiation. Thus extremely bulky stools rich in fat, a low blood calcium, an increased sugar tolerance and a low rather than a high fecal urobilinogen output are characteristic of sprue and not of pernicious anemia. It is probable, however, that these are special symptoms perhaps representing, as stated above, a subtype of the larger syndrome. The matter of the fecal urobilinogen output is receiving increasing attention. It is the most sensitive method for determining the degree of blood destruction. In pernicious anemia, an increased output in the feces is always present. In sprue, as pointed out by Koller,²⁷ the output, as measured in 3 cases, was less than normal.

The duration of the remission in pernicious anemia has recently been studied by Strauss and Pohle.²⁸ The following conclusions are drawn: patients with pernicious anemia who require relatively little liver extract to maintain a normal blood level may relapse in as short a time as two months after liver therapy is omitted; the majority of patients with pernicious anemia cannot be satisfactorily treated by the use of massive doses of liver extract given at intervals of several months; and the optimum interval between injections for most patients is from one to four weeks. Another paper by the same group²⁹ dealing with therapy discussed combined degeneration of the spinal cord, with the results of seven years' experience with parenteral liver therapy. It was found that the neural lesions could be arrested in every case. If adequately treated, no case of pernicious anemia developed new neurologic disturbances. Adequate therapy should maintain the blood at a red-cell level of 4,500,000 or over, the color index at 1.0 or below and the mean corpuscular volume at 100 cu. microns or below; there must be no symptoms of any nature (glossitis, indigestion and so forth) attributable to pernicious anemia; and if there is recurrence of paresthesias or other subjective disturbances, the dose of liver extract must be doubled. Each patient's dosage is an individual matter. The material used by Strauss and his co-workers was a very dilute liver extract (1 unit per cubic centimeter), usually given in 10-cc. amounts weekly, although some patients required the material

three times weekly. In my experience, the highly concentrated extracts are as effective as the dilute extracts, perhaps more so, in treating the neurologic lesions, and they are much preferred by the patient.

HEMOLYTIC ANEMIAS

Interest in this group of cases, which is characterized by increased blood destruction, has developed considerably in the last few years. The hemolytic anemias have been classified as follows³⁰:

- A. Congenital hemolytic icterus (anemia)
 1. Chronic, with or without crisis
 2. Subacute
 3. Acute (crisis)
- B. Acquired hemolytic icterus (anemia)
 1. Secondary to known cause (infectious, chemical, "toxic," pregnancy and so forth)
 2. Symptomatic, in association with certain, usually malignant diseases, as lymphatic leukemia, Hodgkin's disease, carcinomatosis
 3. Of unknown cause, with or without hemolysins in the serum
 - a. Chronic, with or without crisis
 - b. Subacute
 - c. Acute
 - d. Acute fulminating, often with hemoglobinuria

This classification attempts to restore the former well-known grouping of congenital and acquired types, especially since there appears to be an unfortunate tendency to deny the existence of the acquired type.

Spherocytosis. The conception of the spherocyte is important in considering the hemolytic syndromes. About twenty years ago, Naegeli³¹ pointed out that the red cells in congenital hemolytic jaundice tended on the whole to be smaller, rounder and thicker than normal, and he designated them "spherocytes." He believed that the disorder represented an abnormal production of cells in a faulty bone marrow, and that the spherocyte was the pathognomonic cell of the hereditary disease. This statement was universally accepted. In recent years, Haden³² and others found that there was a direct correlation between the degree of thickness of the erythrocyte and its fragility to hypotonic solutions of sodium chloride. More recently, Dameshek and Schwartz³³ found hemolysins in the serum of 2 cases of acutely developing hemolytic anemia, in one of which marked spherocytosis was present. As the patient recovered after splenectomy, the hemolysin was no longer present, the spherocytosis gradually diminished and disappeared, and the saline fragility became nor-

mal. It was reasoned that perhaps the hemolysin and the spherocytosis were related. A hemolytic serum was therefore produced, which, when injected in guinea pigs, resulted in acute or subacute hemolytic anemia, spherocytosis, increased fragility and reticulocytosis. The degree of spherocytosis and anemia varied directly with the amount of hemolytic serum injected. Except for hyperplasia, the bone marrow was normal. These observations have recently been confirmed by Tigertt and Duncan³⁴ in dogs. Thus for the first time it was shown that spherocytosis could be produced without postulating an abnormal bone marrow. Spherocytosis in these experiments was shown to be the end-result of the activity of hemolysin, and the possibility was broached that a spherocyte represented a red cell that had already been damaged by a hemolytic agent. It seems likely that the spherocyte is the forerunner of complete hemolysis. It can be produced by immune hemolytic serums, by various chemicals, such as sulfanilamide, by hypotonic salt solutions and, in fact, by many agents that damage the red cell by various means. Although spherocytes of various conditions are morphologically indistinguishable, they may be quite different from the chemical or physical standpoints.

Mechanism. Although the presence of hemolysins may be the basis of many of the hemolytic syndromes, including acute hemolytic anemia and paroxysmal (cold) hemoglobinuria, Ham and Castle³⁵ have recently stressed the importance of intravascular stasis as a prime cause of increased blood destruction. They point out that the spleen is primarily a stasis organ, and that splenectomy is beneficial because the abnormal spherocytes are no longer subject to the hemolyzing effects of continued stasis in the spleen. They claim that increased agglutination (rather than hemolysis) is at the bottom of the experimental results of Dameshek and Schwartz, and show that a so-called "pure agglutinin" (concanavalin A) produces hemolytic anemia in animals. They point out many clinical applications of the so-called "erythrostatic theory." Although the conclusions of Ham and Castle are in certain respects probably correct (agglutinative hemolytic transfusion reactions, autoagglutinins and so forth), they fail to explain the lack of increased hemolysis in polycythemia—in which stasis is extreme—and in thrombosis of the splenic vein. That various hemolytic agents, free of any agglutinating reaction whatever, can cause hemolytic anemia is also not explained by this theory.

The relation of the spleen to increased hemolysis is still quite obscure. Ham and Castle postulate

for the spleen a simple physical or passive function; they state that the condition of blood incubating in a test tube is in many respects identical with that in the splenic sinusoids. There is a possibility, however, that the spleen participates more "actively," perhaps through obscure cellular mechanisms. After all, the spleen is somewhat more than a test tube. The dramatic effects of splenectomy in many cases of hemolytic anemia are much in favor of this idea, especially in acquired cases when there is frequently a complete reversion of the blood picture to normal. Thus the theory of so-called "hypersplenism" or of hyperactivity of the entire reticuloendothelial system must be considered, at least in some cases.

In summary, it is likely that various mechanisms are responsible for the development of hemolytic processes. Haden,³⁶ in an admirable review of hemolytic anemia, states that the factors in increased hemolysis may be summarized as follows:

- I. Increased hemolysis of normal cells damaged by foreign agents
 - a. Chemicals
 - b. Parasites
 - c. Bacterial toxins
 - d. Amboceptor and complement reactions (including hemolysins and agglutinins)

II. Increased activity of the spleen

The subject of pathogenesis is still in the process of elucidation, and the final word has certainly not been said.

Clinical studies. Farrar, Burnett and Steigman³⁷ found a hemolysin in a case of acute hemolytic anemia that was cured by splenectomy, thus confirming our own observations. Another case of acute hemolytic anemia, with spherocytosis and recovery after splenectomy, is reported by Mandelbaum.³⁸ This case is of interest in that it occurred in a seventy-five-year-old person. It also illustrates to what length writers will go to avoid the designation of acquired hemolytic jaundice. Since spherocytosis was present, a congenital hemolytic process was assumed, even though the patient was seventy-five years old, had no familial history, and had never previously been known to have either splenomegaly, anemia or jaundice. It should be continually stressed that spherocytosis is by no means pathognomonic of the congenital type. In a study of a case of typical hereditary hemolytic jaundice, Waugh and Lamontagne³⁹ make some interesting observations on the types of bilirubin present and on the hypotonic fragility of the erythrocytes. These observations are both carried out by utilizing the photoelectric colorimeter of Evelyn adapted to bilirubin and fragility measurements. Even in hemolytic icterus, a small amount of so-

called "direct" bilirubin was found. The hypotonic fragility, as determined with the photoelectric colorimeter, can be ascertained very accurately and shows very small degrees of hemolysis. With this technic Waugh and Lamontagne demonstrated that before splenectomy a few extremely fragile erythrocytes are present, disappearing after operation.

Careful and well conceived studies of a rare type of hemolytic syndrome—"paroxysmal nocturnal hemoglobinuria"—have been made by Ham⁴⁰ and by Ham and Dingle.⁴¹ Although the fundamental abnormality was found to reside in the red blood cells, a thermolabile factor essential for hemolysis and found in serum (complement) was also essential. The hemoglobinemia and hemoglobinuria were associated with sleep, and it is suggested that during sleep there is an increased intravascular hemolysis associated with increased acidity of the blood, especially of regions of the blood subject to stasis, such as the spleen. Further detailed studies bearing on the immunologic situations involved are described by Ham and Dingle.

A review of the cases of acute hemolytic anemia (acquired hemolytic icterus, acute type) has recently been made.⁴² Many of these have been mis-called "Lederer's anemia," identical cases having been described many years ago by Widál and his collaborators and by Chauffard (1907-1914). These cases are characterized by acute or subacute onset, rapidly progressive anemia, jaundice with out bile in the urine, an increased output of urobilinogen in urine and feces, and a variable blood picture. The concept that these cases are benign and respond to one or two transfusions has become prevalent, the reverse is, however, frequently true. In a number of cases, when several transfusions have been given and the patient has failed to respond, the possible dramatic results of splenectomy have unfortunately been ignored. To be sure, not all patients recover following splenectomy, which indeed is a serious procedure in this age group (usually from forty to sixty five). My routine at the present time is to give one to three transfusions, if no definite therapeutic effect takes place, splenectomy is performed without further ado. If this procedure is postponed, the patient may develop new hemolysins or agglutinins, have severe transfusion reactions, and succumb to a final "last ditch" operation.

Cooley's erythroblastic anemia This disease is receiving increasing attention, and is found chiefly in children of Greek and Italian parentage, being characterized by hemolytic anemia, the presence of large numbers of nucleated red cells and bone changes. The latter are apparently due to marked hyperplasia of the bone marrow with expansion

of the marrow cavities. Both Smith⁴³ and I⁴⁴ have described a new abnormality of the red cells in this disorder, namely, the "target cell." This erythrocyte, the antithesis of the thick spherocyte, is very thin, having the appearance of a bull's eye or target in stained smears, and is unusually resistant to hypotonic salt solutions. It may well be the inherited factor in Cooley's anemia. "Target-cell" anemia⁴⁴ is characterized by bone changes like those of Cooley's anemia, increased blood destruction, and the presence of many target cells with increased resistance to hypotonic salt solution. These cases are important in that they probably represent mild cases of Cooley's anemia, and the patients may reach adulthood and result in the propagation of the more outspoken disorder of Cooley's anemia. Under the title, "A Familial Hemopoietic Disorder in Italian Adolescents and Adults Resembling Mediterranean Disease (Thalassemia)," Wintrobe and his co-workers⁴⁵ describe a number of such cases. The name "target cell" was applied by Barrett.⁴⁶ This interesting cell is seen following splenectomy, in certain hepatic diseases, in Cooley's anemia and in sickle cell anemia.

LEUKOERYTHROBLASTIC ANEMIA

In recent years, interest has developed in a condition characterized clinically by marked splenomegaly, slowly progressive anemia of the normocytic type, leukocytosis with the presence of myelocytes, metamyelocytes and a variable number of nucleated red cells, and irregular bone changes, as demonstrated by x-ray study. Histologically, a fibrotic bone marrow is usually found in association with myeloid transformation of the spleen (ectopic bone marrow activity). The condition has been variously described as leukoerythroblastic anemia (Vaughan⁴⁷), nonleukemic myelosis (Hickling⁴⁸), myelophthisic anemia (Mettier⁴⁹), and agnogenic myeloid metaplasia of the spleen (Jackson, Parker and Lemon⁵⁰). It is probably closely related to or identical with osteosclerotic anemia and in all probability has been confused with myelogenous leukemia, particularly in certain terminal cases of polycythemia vera. As Thompson and Illyne⁵⁰ point out, replacement of the bone marrow by various foreign tissues, such as fibrosis, new bone and carcinoma may result in the above hematologic findings, which are chiefly characterized by a few myelocytes, a disproportionate number of normoblasts and reduced platelets. Jackson, Parker and Lemon point out the slow progressive character of the disorder, the average duration in 10 cases studied being 10.8 years. They give prime importance to the splenic abnormality, classifying it as "agnogenic myeloid metaplasia," that is, there is ectopic bone marrow growth of un-

known or indeterminate origin in the spleen. They rate the bone-marrow findings as of secondary importance. This is contrary to the experience and interpretation of other observers, who agree that the splenic changes are secondary to replacement of bone marrow by abnormal tissue. Emphasis on the splenic changes has led Jackson et al. to conclude that even certain cases of acute or subacute hemolytic anemia with myeloid metaplasia of the spleen are included in this syndrome. Hemolytic anemia is characterized by a very hyperplastic bone marrow and often by bone-marrow activity in other organs; the syndrome described by Vaughan, Hickling, Thompson, Mettier and others presents a bone marrow that is replaced by foreign, usually fibroblastic, tissue. Although the splenic lesions may be similar, it is probable that the conditions are entirely distinct.

Marked splenomegaly, anemia, a moderate elevation in the leukocyte count, myelocytes and nucleated red cells have generally led to the erroneous diagnosis of chronic myelogenous leukemia and to x-ray therapy. This treatment is exactly wrong, since the spleen is apparently trying desperately to fulfill the functions of the replaced marrow. The differential diagnosis from leukemia may be very difficult. It is well to remember that this picture may be the end-result of previous bone-marrow disease, whether polycythemia, osteosclerosis or metastatic malignancy, and that the terminal picture is nonspecific. Only a bone-marrow biopsy by the trephine method will surely settle the diagnosis in most cases. A puncture biopsy usually gives inconclusive results, since the marrow is hypocellular; removal of a button of sternal bone reveals the bone-marrow lesion, which is usually fibrosis, but may show, as Mettier⁴⁸ has pointed out in 10 interesting cases, osteosclerosis, Gaucher's disease, carcinomatosis, neurofibromatosis and multiple myeloma. These histologic features are readily distinguished from myelogenous leukemia. X-ray examination of the femurs may show spotty areas of diminished and increased density, and as Vaughan⁴⁶ has pointed out, the paucity of the x-ray findings is often surprising in view of the extensive replacement of bone by fibrous tissue, as seen at post-mortem examination.

POLYCYTHEMIA VERA

This disease of unknown origin is characterized by extensive hyperplasia of the entire bone marrow, with the result that the red cells, leukocytes and platelets become greatly increased in the peripheral blood. The great increase in circulating red-cell mass results in the establishment of a very viscous, slow-moving circulation. The combination of a

greatly distended circulation and a tendency to multiple thromboses accounts for the majority of the symptoms of the disorder. These are described by Dameshek and Henstell.⁵¹ These authors point out that the multiplicity of symptoms may result in the diagnosis of psychoneurosis, or if one set of symptoms is outstanding, in such diagnoses as nephritis, cardiovascular disease, migraine or peripheral vascular disease. The blood-platelet count is usually extremely high, and with the sluggish circulation and the increased blood viscosity, thrombotic manifestations are common. These frequently occur in the extremities, simulating thromboangiitis obliterans, but are not infrequently present internally. Thus cerebral thrombosis, coronary thrombosis (Miller⁵²) hepatic-vein thrombosis and portal-vein thrombosis may occur. Since many cases go unrecognized for a number of years, being treated for menopause, migraine, heart disease and so forth, it should be the rule to perform a red-cell count—not a Tallqvist hemoglobin—in any patient whose plethoric appearance makes one suspect polycythemia. Further clinical diagnostic aids are distended retinal veins, splenomegaly and hepatomegaly, and flushed mucous membranes. The erythrocyte count usually gives the diagnosis, although in doubtful cases the hematocrit, blood volume and leukocytes and platelet counts are all necessary.

Most patients go along for many years in various degrees of discomfort. The development of the degenerative diseases is accelerated, and death is usually the result of nephritis, coronary disease or a cerebral accident. In 3 of 40 cases which were followed, anemia gradually developed in association with leukocytosis and the presence of immature granulocytes and nucleated erythrocytes. Are these cases of chronic myelogenous leukemia, or do they represent fibrosis of the marrow with myeloid metaplasia of the spleen? Most observers have considered that the polycythemic condition became transformed into leukemia, but it becomes increasingly evident that these cases are not truly leukemic, but that the blood picture is simply leukemoid in type in association with a fibrotic bone marrow and a spleen that is actively attempting to produce bone-marrow cells. It is likely that the majority of the cases of leukoerythroblastic anemia, as pointed out above, have previously been unrecognized examples of polycythemia.

The best treatment for polycythemia is still being debated. X-ray therapy over bones (and marrow) and treatment with phenylhydrazine, Fowler's solution or radioactive phosphorus have all been advocated. Potentially or actually all these methods are dangerous. The induction of an iron-

deficiency state has proved safe and therapeutically effective. Venesections of 500 cc. of blood are performed twice weekly until the hemoglobin is reduced to approximately 80 per cent and the erythrocyte count to approximately 5,000,000. This usually takes from six to eight venesections. The patient is then placed on a low-iron diet, that is, restricted in meats, liver, eggs, green vegetables and rye bread. The combination of a great loss of iron (hemoglobin), together with a continued low intake of iron, results in a sustained iron-deficiency state with relatively low values for hemoglobin. The erythrocyte count under this regime gradually rises to between 7,000,000 and 8,000,000, but with the iron deficiency, the values for hemoglobin, hematocrit and red-cell mass remain low for periods of six to twelve months (average eight months). The method is safe and physiologically sound, and requires but little supervision after the first series of venesections. Estimations of the hemoglobin and hematocrit percentages become of far greater value than the erythrocyte counts.

HEMOPHILIA

Work on the nature of hemophilia continues to be pursued at the Thorndike Memorial Laboratory in Boston. It was previously shown that the clot-promoting power of normal plasma was present in the globulin fraction of the plasma, from which an extract containing so-called "globulin substance" could be prepared by acid precipitation. More recent work by Lozner and Taylor⁵³ demonstrated that the effective clot-promoting material was found in plasma euglobulin (plasma proteins insoluble in distilled water, soluble in isotonic saline). It is, of course, hoped that further fractionation will result in the development of an extract effective in the continued treatment of hemophilia, that is, in keeping the blood coagulation time at normal levels. At present, the only definitely effective treatment aside from the topical application of globulin substance is in acute hemorrhage, which is handled either by a transfusion of whole blood or plasma, or by the use of plasma euglobulin.

Brinkhous⁵⁴ presents a somewhat different concept regarding the pathogenesis of hemophilia. Studies made by this observer demonstrated that in hemophilic blood the prothrombin was converted to thrombin unusually slowly. This delay in prothrombin conversion could be corrected by adding less than 1 mg. of crude thromboplastin to 100 cc. of the abnormal blood. Brinkhous believes that the beneficial effects of transfusion are due to the addition of thromboplastin, which is derived from cells and platelets. Quick⁵⁵ has come to the same conclusion.

Aggeler and Lucia⁵⁶ have rendered a valuable service in investigating the potency of a large number (seventeen in all) of so-called "blood-coagulating substances." They found that the claims made for these preparations were, to say the least, greatly exaggerated. Most of them were completely inactive. Only those substances suitable for local use (like certain snake venoms) were at all active. Similar studies are reported by McGavack.⁵⁷ In the light of these investigations, the alleged effects of oxalic acid intravenously in the treatment of hemophilia must be greatly discounted. A report on the use of this chemical is that of Page, Russell and Rosenthal,⁵⁸ who claim a good effect in 3 cases of hemophilia by the use of repeated intravenous injections of 5 to 10 mg. The actual case reports, however, are quite unconvincing, and it is reassuring that the conclusion is made that "its use, along with other known beneficial measures, notably multiple transfusions [*italics mine*], would be warranted in attempting to control bleeding in hemophilia." McGavack also reports on the use of a substance (Koagmin) similar to oxalic acid in the treatment of hemophilia. This is an extract derived from the weed, shepherd's-purse, and contains dicarboxylic acids. In 4 cases of hemophilia treated with this material prompt shortening of the coagulation time lasted for two to four hours.

An excellent article on certain effects of hemophilia on the growing skeleton is contributed by Caffey and Schlesinger.⁵⁹ Simple hemarthrosis, panarthritis and superiosteal hemorrhage are all carefully considered. An interesting hemorrhagic diathesis with prolonged coagulation time, associated with a circulating anticoagulant, is reported by Lozner, Jolliffe and Taylor.⁶⁰ The case differed from hemophilia not only clinically but in certain physiologic respects: a transfusion failed to shorten the clotting time, and normal human plasma and globulin substance were ineffective *in vitro*. A striking finding was the presence in the blood of a substance interfering with the completion of the normal clotting mechanism. When the patient's plasma was tested *in vitro* against whole normal blood, clotting was prevented. The circulating anticoagulant might have been in some manner associated with the general lymph-node tuberculosis present.

PURPURA

Thrombocytopenic purpura. The pathology of the bone marrow in idiopathic thrombocytopenic purpura has been studied by Limarzi and Schleicher.⁶¹ A uniform finding was marked hyperplasia (increase) of megakaryocytes, with a shift

to young forms; this was particularly striking in the chronic form. Speculation is made regarding the possibility that the spleen in this disease may have an unusual inhibitory effect on platelet production by the bone-marrow megakaryocytes. This is confirmed by some recent unpublished work of Dr. E. B. Miller and myself. Despite the almost complete absence of platelets from the circulating blood, the bone marrow is crowded with megakaryocytes that produce few if any platelets. Directly following splenectomy, there is a striking increase in platelet production by the megakaryocytes, reflected quickly in the peripheral blood by a rapid increase in the platelet count.

On the other hand, Wiseman, Doan and Wilson⁶² state that "sternal marrow studies have consistently revealed normal numbers of normal appearing megakaryocytes in a normal cellular setting." They also state that they are convinced, from their supravital studies, that there is increased activity of splenic clasmatoocytes in destruction of platelets. In other words, they maintain that the marrow is normal, but the spleen is destroying an increased number of platelets in the disease. As diagnostic essentials of idiopathic thrombocytopenic purpura, Wiseman et al. list: spontaneous purpura with or without free bleeding from the mucous membranes, definite decrease in the blood platelets, normal coagulation and prothrombin times, no unusual anemia or leukocytosis, absence of pathologic cells in both the blood and the marrow, absence of recent history of the ingestion of drugs, and lack of appreciable enlargement of the spleen or lymph nodes. Regarding therapy, x-ray treatment over the spleen is considered worthless, the use of snake venom "has not been encouraging," and parathyroid extract was tried without favorable result. Transfusions help to tide the patient over until either a spontaneous remission becomes established or splenectomy is performed. It is gratifying to note that "full doses" of blood are recommended, in contradistinction to the encomiums of various authors for the use of small transfusions. Why small transfusions should possess any special virtue is a mystery I have never been able to fathom. Splenectomy is the only real cure. In the chronic case, the decision for splenectomy must be made only after repeated observations of the patient's course. The acute cases demand energetic action, which may be summarized as follows: confirmation of the diagnosis by sternal puncture; immediate transfusions; if blood loss persists, splenectomy. Of 9 splenectomized patients, 1 died of postoperative shock, and the others made uneventful recoveries. It has been my experience

in several cases that too much temporizing and indecision regarding splenectomy have led to cerebral hemorrhage and death. In the acute case, a quick decision must be made and splenectomy immediately performed, before the patient has had a chance to bleed into vital tissues.

Thrombocytopenic purpura in relation to the menarche is discussed by Goldburgh and Gouley.⁶¹ Pubertal menorrhagia may be the first indication of purpura. Splenectomy is curative and is indicated when repeated transfusions of blood and endocrine therapy have failed to check the hemorrhagic tendency.

Nonthrombocytopenic purpura. Purpura occurs either when the blood platelets become extremely low or when there is damage to the capillary walls. Such cases are divided, respectively, into thrombocytopenic purpura and vascular purpura; in the former the platelet count is low, the bleeding time increased, and the clot retraction poor, whereas in the latter the platelet count is normal, the bleeding time normal or somewhat increased and the clot retraction normal. In both conditions the clotting time is normal and the tourniquet test positive.

Most cases of purpura fall into these two groups. There are rare cases, however, in which, although the platelet count is normal, the platelets themselves are abnormal. These cases may be familial; because of the platelet abnormality, clot retraction is poor and the bleeding time is prolonged. Other familial cases of purpura are probably exaggerated forms of vascular purpura, in which the bleeding time is prolonged although the platelet count, platelet morphology and clot retraction are normal. Bruun,⁶⁴ reporting a large family of bleeders, prefers the designation "hereditary hemorrhagic diathesis" for these cases, which have been termed "pseudohemophilia" by von Willebrand⁶⁵ and others. In Bruun's cases, a hemorrhagic tendency present in both sexes had been present in four generations and in 15 of 23 members of the family. Four patients had bled to death. The outstanding abnormality was a greatly prolonged bleeding time (over an hour), with normal platelets and a normal platelet count, the tourniquet test being either normal or slightly positive.

A quite benign familial abnormality is described by Davis⁶⁶ under the name "hereditary familial purpura simplex." Spontaneous ecchymoses, mostly in women, were the presenting symptom. Diligent examination of the families demonstrated numerous other cases. No hematologic abnormalities were found, the only finding being a positive capillary resistance test in 16 of 25 cases tested. One family also showed hereditary telangiectasia

(Osler-Rendu-Weber disease). Rheumatoid arthritis and rheumatic fever were common in the families studied.

For topical application in cases of vascular purpura and perhaps in other hemorrhagic conditions, including hemophilia in which the bleeding point can be visualized, the use of Russell viper venom (Stypven) has been recommended by Page and Thomas.⁶⁷ Pledgets soaked in the solution are applied directly to the bleeding point; all intervening clots or other obstructions must be cleared away. Packing is sometimes advantageous. The venom may also be dropped directly onto the hemorrhagic area from the point of a small-caliber hypodermic needle. Sprays of venom from an atomizer may be used in the nasopharynx or to control bleeding from the uterine cervix. The Russell viper venom appears to accelerate the action of thromboplastic substances and to act with the latter in a synergistic manner.

HYPOTHROMBINEMIA

The recognition, careful study and treatment of hypoprothrombinemia, or vitamin K deficiency, represent one of the milestones of medical progress of the past decade. The story of vitamin K, its deficiency and its value in clinical medicine is well known. For the interested reader, the review by Quick⁶⁸ is recommended. The test that has proved of greatest value in determining the prothrombin time is that of Quick.⁶⁸ An important advance in performance of the test, as described by Souter, Kark and Taylor⁶⁹ is the preparation of a stable thromboplastin. This is a lyophilized rabbit-brain extract that can be kept indefinitely. Before use it is suspended in salt solution.

Vitamin K deficiency may develop in conditions other than obstructive jaundice: inadequate dietary, particularly of fats, impaired gastrointestinal digestion, unusual loss of fats from the bowel and severe hepatic damage. Prolonged dietary deficiency as a cause of hypoprothrombinemia is emphasized by Kark and Lozner.⁷⁰ In the 4 cases studied, multiple deficiencies were present (scurvy, subclinical pellagra), thus offering further evidence that nutritional deficiency in man is rarely, if ever, confined to a single factor. In newborn infants a potential hypoprothrombinemia is probably usually present, and in some infants a hemorrhagic tendency associated with excessively low prothrombin values may be present. Quick and Grossman⁷¹ found that the prothrombin concentration of infants' blood, nearly normal at birth, drops abruptly during the first few days of life, and then usually recovers rapidly. The quick recovery is thought to be due to the establishment of

the normal bacterial flora in the intestines, with resultant initiation of the synthesis of vitamin K. Hemorrhagic disease of the newborn is due to a delayed restoration of the prothrombin level. Although the condition may be very severe, it is promptly cured by the oral administration of vitamin K. Poncher and Kato⁷² describe a micro-method for the determination of prothrombin, and report on the treatment of 22 infants with hypoprothrombinemia. The average prothrombin time of 10 patients before treatment was 210 seconds (normal, about 25 seconds), and in 12 other patients was more than 300 seconds. Synthetic preparations of vitamin K were administered either orally, intramuscularly or subcutaneously. A therapeutic effect was present within two to six hours. Transfusions were not necessary. Shettles, Delfs and Hellman⁷³ make the important observation that the plasma-prothrombin level of the newborn infant can be increased not only by feeding vitamin K concentrate directly to the infant after birth, but by administering it to the mother prior to delivery. The values obtained with maternal administration are often three times those normally seen, and in general are higher than can be attained by administering vitamin K concentrate to the newborn infant.

The treatment of vitamin K deficiency is becoming much simpler with the elaboration of numerous synthetic products, some of which may be given parenterally. Kark and Souter⁷⁴ report on the treatment of 18 patients with hypoprothrombinemia by the parenteral administration of a water-soluble derivative of 2-methyl,1,4-naphthoquinone. Within a few hours of the intravenous or intramuscular administration of the material, the bleeding was satisfactorily controlled and the prothrombin time was normal. On the other hand, 12 patients with hypoprothrombinemia associated with hepatic disease did not respond to intensive parenteral administration. Thus, if the prothrombin time of a patient with jaundice fails to become normal after treatment, it is evident that hepatic disease is present and the prognosis poor. Andrus and Lord⁷⁵ administered 2-methyl,1,4-naphthoquinone dissolved in corn oil intramuscularly. Single injections intramuscularly of as little as 2 mg. in 2 cc. of oil restored the plasma prothrombin level by as much as 48 per cent, an effect that became evident within eight hours after injection and might be prolonged for as long as a week.

SPLENIC DISEASE

Very little that is new has been reported during the past year on this subject. The pathogenesis of so-called "Banti's disease" is discussed by

Thompson⁷⁶ on the basis of 137 well-studied cases falling into the general category. It was found that the condition resulted from a variety of primary lesions that produce splenic-vein hypertension. The conclusion is made that the syndrome is a secondary mechanical congestive splenomegaly and that there is no reason for assuming the presence of an unknown toxic agent or for retaining the concept of three stages in the development of Banti's disease. Cirrhosis of the liver exists only as one of several obstructive mechanisms (it was present in 68 per cent of the cases); if it is not present at the time of splenectomy, it will not develop subsequently. The splenic histology is the same in all types. Extrahepatic lesions responsible for congestive splenomegaly, which is suggested as a better term than Banti's disease, are thrombosis of the portal or splenic veins and compression of the splenic vein (in infants and children).

A somewhat different interpretation of the Banti syndrome is that of Ravenna,⁷⁷ who believes that the condition is a "fibrocongestive splenomegaly." Although this author concludes that the condition is due largely to splenic congestion, he suggests that this may be caused by "primary" lesions of the small splenic arteries that regulate the flow of blood into the spleen, with secondary portal hypertension. That the Banti syndrome cannot be clinically differentiated from cases of cirrhosis of the liver in which portal hypertension is definitely primary is not discussed. It seems that the views of Thompson and his co-workers adequately explain the pathogenesis of the great majority of the cases, although it cannot be denied that an occasional case may be better explained by Ravenna's thesis.

The removal of very large spleens is discussed by Henry,⁷⁸ who has had considerable experience in the tropics. It is emphasized that splenectomy in these cases frequently results in a relaxation of the diaphragm caused by "loss of the cushion on which it has long been moulded and stretched." It is well known that chest complications are frequent following splenectomy, and to obviate these effects, Henry recommends the use of a rubber balloon attached to a source of carbon dioxide and left in place under the diaphragm in the splenic bed after removal of the spleen. The balloon may be gradually deflated and removed after a few days.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 27171

PRESENTATION OF CASE

First Admission. A fifty-eight-year-old garage-man entered the hospital complaining of weakness, dizziness, exertional dyspnea and numbness in the fingers.

Two years before admission he noticed slight discomfort around and below his umbilicus, which occurred half an hour after meals and was worse in the morning. This was followed by nausea without vomiting, and gradual subsidence of the symptoms by the next mealtime. Eighteen months before admission numbness and aching appeared in the calves during activity, and the patient found it necessary to watch his feet while walking and lost his balance when his eyes were closed. One year prior to entry dyspnea on exertion developed, and some time later he suffered from transient soreness of the gums and hard palate. Six weeks before admission marked the onset of weakness, lethargy and inability to concentrate, and a sensation of "pins and needles" appeared in the hands and feet, with "deep bone" soreness and swelling of the feet. The numbness and cramps in his legs and feet increased and often awakened him at night; relief could be obtained only by exercise. The patient had not lost more than 7 pounds in weight.

The family history was irrelevant. Fourteen years before admission the patient had had an attack of epigastric pain and jaundice and was told that he was anemic. At forty-five he had had three attacks of gonorrhea in rapid succession. No occupational hazard could be elicited. Although his diet seemed adequate the patient ate very little meat.

On examination the patient was well developed and well nourished and in no apparent distress. The skin had a sallow lemon tint, with questionable icterus of the scleras. The mucous membranes were pale, and the tongue thick and smooth, with atrophy of the papillas. There was cardiac enlargement, and a soft blowing apical systolic murmur, but the blood pressure was 120 systolic, 60 diastolic. Pitting edema of the feet and ankles was present, and muscle tenderness in the calves. The knee jerks were hyperactive; vibration sense was

diminished at the ankles, but position sense was fairly good in the great toes. The gait was a little waddling with a positive Romberg sign.

The temperature was 99.5°F., the pulse 93, the respirations 22.

The urine was normal. The blood showed a red-cell count of 1,230,000 with a hemoglobin of 40 per cent, and a white-cell count of 3850 with 60 per cent polymorphonuclears; the platelets were diminished. The red cells showed pronounced poikilocytosis, anisocytosis and some polychromophilia, with many large cells well filled with hemoglobin. The serum van den Bergh was slightly above normal, the icteric index 7. The serum proteins were 6.1 gm. per 100 cc., and the chlorides were equivalent to 109 cc. N/10 sodium chloride. A blood Hinton test was negative. Gastric analysis revealed achlorhydria.

A gastrointestinal series was negative.

The patient was given intramuscular liver injections and a high-vitamin, high-calorie diet. The reticulocytic response was satisfactory, and he improved symptomatically, being discharged to the Out Patient Department three weeks after admission, when the red-cell count was 3,590,000, and the hemoglobin 60 per cent.

Second Admission (five years later). The patient was followed in the Out Patient Department for two years, where he was given intramuscular injections of liver extract once a week, the red-cell blood count remaining around 4,500,000 with a hemoglobin of 80 per cent. For the next two years he made his own oral preparation according to recipe, but for more than a year before admission he had had no liver preparation whatever, and made little effort to include it in his diet. One month before admission, dizziness, weakness, dyspnea, and numbness in the fingers returned and increased so that once again he came to the hospital.

Physical examination was as before, including the neurologic findings and peripheral edema. The upper border of the liver was at the sixth space while the lower border was percussed three finger breadths below the costal margin in the mid-clavicular line.

The blood showed a red-cell count of 1,770,000 with a hemoglobin of 54 per cent, and a white-cell count of 1800; the platelets were reduced. The red cells showed poikilocytosis, anisocytosis and macrocytosis. The serum van den Bergh was 2.1 mg. per 100 cc., biphasic, and the nonprotein nitrogen 32 mg. The stools were normal.

A gastrointestinal series showed the folds of the stomach to be widened. Arising from the greater curvature and posterior wall of the antrum of the stomach was a broadly based, slightly lobulated

tumor mass, approximately 25 cm in width. An electrocardiographic recording showed normal rhythm with a rate of 100 and a PR interval of 0.15 second; P waves were not visualized well in Leads 1 and 2, and there was a tendency to left-axis deviation.

On gastroscopic examination the mucosa throughout the stomach was very pale and smooth, but normal to large rugae were present and the blood vessels were not seen shining through the mucosa. In the antrum there appeared to be a smooth nonulcerated polypoid mass. The patient remained in the hospital for three weeks and made a good response to intramuscular injections of liver extract.

Third Admission (ten days later). The patient remained at home, then returned to the hospital. An operation was performed three days after admission, following two 500 cc. blood transfusions.

DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON: This is a typical story of pernicious anemia with combined system disease. The most interesting feature develops toward the end of the story and concerns the nature of the gastric tumor.

The history is quite consistent with pernicious anemia, and all the symptoms can be explained on that basis. Whether the nausea without vomiting can be explained on that basis alone is perhaps not certain. I think it probably should be explained in that way.

"... and was told that he was anemic." I am going to leave that and not come back to it. It could have been the onset of pernicious anemia fourteen years previously but more likely had nothing to do with his illness. The tongue was thick, and one does not usually get a thick tongue in pernicious anemia—it is usually in iron-lack anemia that the tongue is thick and boggy.

The argument whether or not patients with combined system disease can be improved is often raised. Symptomatically they do improve with massive doses of liver extract. I believe that it is wise to give these patients a crude preparation of liver by mouth, as well as parenteral liver. There have been pathologists who argue that you cannot get improvement in combined system disease because the pathological findings are inconsistent with any reversible change; but given a patient with symptoms, one does not know what the disease of that cord is. I am sure you can get improvement in central nervous system symptoms with liver, and in the early stages the changes are reversible. I think it is true that the longer the symptoms exist the less likely they are to improve, and I know it is true that ataxia is much easier to treat than spasticity.

A strange thing about patients with pernicious anemia in relapse is that they get frightfully stubborn. You can talk to them and explain the whole situation. However, following treatment they feel so well they say, "Perhaps that doctor was wrong. I shall stop liver and see what happens." They stop, and they get worse. Finally the old symptoms return. Then they get stubborn and think of every conceivable reason why they are going downhill rather than the obvious one—that they are not getting liver. It is always dangerous to stop liver for the purpose of discovering whether patients actually need to continue it. It is necessary sometimes but requires great care in follow-up.

May we look at the x ray films?

DR JAMES R. LINGLEY: I cannot add to the report in the record. The films show this mass arising from the greater curvature, starting about 5 cm. above the pylorus. The mass is sharply defined and slightly lobulated, and there is some spasm of the antrum but no definite rigidity of the lesser curvature. It is larger than the usual polyp and more consistent with cancer.

DR RICHARDSON: Dr. Benedict, do you want to say anything in regard to the gastroscopy in addition to what I have read?

DR EDWARD B. BENEDICT: The mucosa was smooth and pale, but the blood vessels were not visible, a finding that is an indication that the mucosa was not really atrophic. Very likely the absence of complete atrophy was because the patient had had liver therapy. The polypoid mass was smooth and round, one could not be sure whether it was an adenoma or cancer.

DR. RICHARDSON: The problem of whether or not this lesion was malignant is absolutely impossible to solve clinically, and may even be difficult for Dr. Mallory. In the first 100 cases of pernicious anemia that we studied here after liver therapy was begun, there were 4 patients in whom we found polyps, and if Dr. Benedict had been here with his gastroscope, we should have undoubtedly found more. I do not know where he would put the incidence of polyps in the stomach with Addisonian anemia, but I should think it would be around 15 or 20 per cent. Is that high?

DR. BENEDICT: I have no figures, but I should think that is a little high.

DR. RICHARDSON: It is my impression that in the old days before liver therapy those patients who had remissions and relapses with no specific therapy developed polyps in much larger proportion than our patients do now. If a fairly high percentage of patients with pernicious anemia develop polyps, and if a fairly high percentage of the polyps become malignant, then one would expect that carcinoma would develop frequently in per-

nicious anemia. In my experience, however, it is rare to find carcinoma in a patient who has definite pernicious anemia. Of course one may see secondary types of macrocytic anemia with a widespread cancerous involvement of the stomach. I think, therefore, that when these patients with pernicious anemia are treated with liver the mucous membrane improves in its general consistence, and polyps no longer develop. This man probably would not have developed a tumor if he had maintained his liver intake.

Is this tumor malignant? I am going to guess that it is not, but there is no real basis for making a guess. One other point, I question the advisability, — and Dr. Sweet will perhaps disagree with me on this, — if one is contemplating a fairly radical gastric operation, of giving two 500-cc. blood transfusions preoperatively in a patient who presumably has had time to restore his blood volume and blood level to normal. Is it not taking an unnecessary risk? May you not get a transfusion reaction, not necessarily due to incompatibility, that will make the postoperative course more stormy than it need be?

DR. RICHARD H. SWEET: I agree with that absolutely. When the blood is up to normal, I see no indication for transfusion. We see reactions not infrequently, and I have seen some lately, especially in patients with an anemia. They occur with properly grouped bloods, and no adequate explanation has been found for them. Although we always postpone the operation in such a case, I have never known such a reaction to be responsible for postoperative difficulties.

DR. RICHARDSON: I thought that you might operate in a period before the reaction occurred, because many are delayed.

DR. SWEET: That is correct, and I do not like to transfuse my patients and operate immediately. I usually do it two or three days ahead of time.

DR. RICHARDSON: To summarize, I think this is a case of Addisonian anemia in a patient who eventually developed a polyp in the stomach; the polyp was removed and I hope it will prove to be benign, that is, without any malignant degeneration.

DR. BENEDICT: I do not quite agree with what you say in regard to the incidence of malignant degeneration. In a study of adenomatous polyps of the stomach, Dr. Allen and I* found that 40 per cent became malignant. In this particular patient I thought that the adenoma was of such a size it probably was malignant. I have seen quite a number of patients with pernicious anemia and carcinoma, and believe that all patients with per-

nicious anemia should have gastrointestinal series and gastroscopic examinations at frequent intervals.

DR. RICHARDSON: Even when they have had adequate treatment?

DR. BENEDICT: Yes.

DR. RICHARDSON: I do not believe that. Have you any figures?

DR. BENEDICT: No.

DR. TRACY B. MALLORY: There are a number of studies accumulating which tend to show that patients who eventually develop carcinoma of the stomach have had gastric anacidity for years. On this basis it has been argued that a persistent anacidity in a young person may be considered a strong indication that that patient is likely to develop cancer of the stomach.

CLINICAL DIAGNOSES

Pernicious anemia.

Carcinoma of the stomach.

DR. RICHARDSON'S DIAGNOSES

Pernicious (Addisonian) anemia, with combined system disease.

Adenomatous polyp of stomach (benign?).

ANATOMICAL DIAGNOSIS

Polypoid carcinoma of the stomach.

PATHOLOGICAL DISCUSSION

DR. MALLORY: Gastric resection was done, and an obvious tumor was found in the stomach. It did not look in the resected specimen very much as it does in the x-ray films. There it seemed to be a definitely polypoid tumor, projecting a considerable distance into the lumen of the stomach. We found a distinctly flat, wide lesion. It did not look particularly polypoid. Post-mortem relaxation of the gastric musculature, particularly, I suspect, of the muscularis mucosae, is the probable explanation. The base was not detectably indurated. On microscopic examination, beginning sharply at each edge of the polyp, the glandular tissue was markedly atypical. The cells were rapidly growing, with many mitotic figures, and the nuclei were hyperchromic and quite disoriented. Cytologically there could be no doubt that the tissue was malignant. Throughout most of the tumor there was no sign of invasion, but in the center of one section we did find a definite spot of invasion extending only 1 mm. below the muscularis mucosae. Therefore, this is not merely carcinoma in situ but has to be regarded as established cancer.

DR. RICHARDSON: I agree that patients with

*Benedict, E. B. and Allen, A. W. Adenomatous polypi of the stomach. *Surg., Gynec. & Obst.* 58:79 64, 1934.

pernicious anemia should be studied for carcinoma, but what I rather question is, if they are adequately treated, must one then feel obliged to continue gastrointestinal x rays at frequent intervals?

DR BENEDICT I think that these patients should be followed by x ray studies and by gastroscopy at least three times a year. Perhaps you would say that the patients with pernicious anemia and cancer whom I have in mind were not adequately treated with liver, but they were under observation in this hospital by good men.

CASE 27172

PRESENTATION OF CASE

A fifty two year-old woman entered the hospital complaining of nausea and vomiting of two days' duration.

Six months before admission the patient first noticed slight vaginal bleeding occurring at irregular intervals. She consulted her physician, and a biopsy was taken of the cervix, which was reported as carcinoma. Following this diagnosis the patient was given twenty x ray treatments at another hospital and remained well until two months before admission, when she began to suffer from frequency, incontinence and severe burning during and immediately following urination. Bladder irrigations gave some relief, but occasionally she noticed small blood clots in the urine and gradually an aching pain developed in her entire pelvis and upper thighs. A cystoscopic examination one week before admission was said to have revealed involvement of the bladder by tumor. The patient had always been troubled by constipation, but this had increased appreciably during the last two months and blood occasionally appeared in the stools. Two days before admission persistent nausea, vomiting and obstipation appeared, but there was no pain or abdominal distention.

Twelve years before admission the patient had had a supravaginal hysterectomy for leiomyomas. Her father had died at seventy two of cancer of the bowel.

The patient was in no apparent distress, but was pale with a questionable icteric tint to the skin and scleras. The heart and lungs were normal, the blood pressure was 130 systolic, 80 diastolic. There was a healed suprapubic surgical incision, the abdomen was soft, with moderate suprapubic tenderness. Rectal examination was negative.

The temperature, pulse and respirations were normal.

The urine showed a ++ test for albumin, and the sediment contained 15 white cells and 2 red cells per high power field, with many bacteria, a culture yielded an abundant growth of alpha hemolytic

streptococci. The blood showed a red cell count of 4,100,000 with 89 gm of hemoglobin (photoelectric cell technique), and a white-cell count of 10,500. The nonprotein nitrogen of the blood serum was 17 mg per 100 cc, and the chlorides 999 milliequiv and the carbon dioxide combining power 23.1 milliequiv per liter, a serum van den Bergh was normal, and the blood Hinton reaction negative. Examination of the stools was negative.

A plain x ray film of the abdomen showed a large amount of gas and fecal material in the colon. There were some gas filled loops of small bowel in the midabdomen, but these were not dilated.

During hospitalization the patient was drowsy, and became nauseated and vomited from time to time, satisfactory bowel movements were obtained with the help of enemas. Gradually her urinary output dropped, and two weeks after admission the nonprotein nitrogen was 100 mg per 100 cc, and the chlorides 102 milliequiv per liter. She developed uremic twitchings and anuria. Finally drowsiness deepened to coma, and the signs of bronchopneumonia appeared. Death occurred three weeks after admission.

DIFFERENTIAL DIAGNOSIS

DR RICHARD CHUTE Here we have a fifty two year-old woman with carcinoma of the cervix, proved six months previously. At that time she was given twenty x ray treatments at another hospital, presumably of 200 to 300 r apiece so that we may guess she received a total of 4000 to 6000 r, focused on the carcinoma of the cervix. That would be enough to cause a regression of the disease, but in most cases would not be enough to destroy the carcinoma completely. Therefore, in my opinion, the carcinoma was arrested but probably not destroyed. Four months afterward, — two weeks before admission, — she had frequency, incontinence and burning, and noticed some small blood clots in the urine. Cystoscopic examination a week before admission was said to have revealed extension of the tumor into the bladder, a happening which is frequent in carcinoma of the cervix. She noticed pain in the pelvis and upper thighs, which would also suggest extension of the tumor into the tissues of the pelvis. Blood occasionally appeared in the stools, this suggests the possibility that the rectum had been invaded by the carcinoma, but rectal examination later on was negative, and one examination of the stools was negative, so that I am going to guess that this blood was due to hemorrhoids, not to rectal involvement.

The supravaginal hysterectomy for leiomyomas twelve years before probably had nothing to do with the present picture except that it is too

bad that the cervix was not also taken out at that time. There was a family history of carcinoma. Two days before admission, that is, six months after her trouble began and several months after the x-ray therapy, nausea, vomiting and obstipation appeared, but no pain or abdominal distention. When she came in she had a moderate secondary anemia. It is said that she had a questionable icteric tint to the skin, but later on the van den Bergh test was reported as normal, so that I doubt the jaundice. The urine showed some blood, which would be consistent with involvement of the bladder with tumor—a few pus cells and alpha-hemolytic streptococci are fairly frequently found in the urinary tract and usually do not have serious pathological significance. The nonprotein nitrogen, the chlorides and the carbon dioxide combining power were essentially normal.

The patient was drowsy, nauseated and vomited from time to time, and her abdomen was somewhat distended at the end. Gradually the urinary output dropped. Two weeks after admission the nonprotein nitrogen had risen to 100 mg. per 100 cc. and she developed uremic twitching and anuria, dying from what I suppose was uremia, with terminal bronchopneumonia.

Jaffe, Meigs, Graves and Kickham* have shown that a great proportion of patients with carcinoma of the cervix die in uremia from obstruction of the ureters. This is usually due to tumor growth, or to tumor that has been fibrosed by radiation therapy. Sometimes the constriction of the ureters is entirely due to fibrosis following radiation therapy, without any tumor tissue's playing a part in producing the constriction. In some cases the carcinoma of the cervix has been completely cured, but ureteral occlusion by postradiation fibrosis has been responsible for death.

It would seem to me that we are dealing in this case with a carcinoma of the cervix that had had inadequate x-ray therapy, and that had extended through the pelvis, involving the bladder and the ureters. Also it is possible that the ureters were constricted purely by fibrosis following radiation therapy, without tumor's playing a part, but my guess is that tumor was actually obstructing them. Therefore, I am going to make a diagnosis of carcinoma of the cervix involving the ureter, with extension to the bladder, bilateral hydroureter and hydronephrosis.

DR. F. DENNETTE ADAMS: May I ask Dr. Chute if he believes that carcinoma of the cervix can be cured by irradiation? He made a distinction

between destruction of the tumor and arrest of the disease.

DR. CHUTE: I do believe that carcinoma of the cervix can be cured by irradiation therapy, but I do not believe that it can be cured with 4000 to 6000 r delivered through the skin by an x-ray machine.

DR. ADAMS: But do you believe it can be cured by irradiation?

DR. CHUTE: My opinion is that an early carcinoma of the cervix can probably be cured by a combination of radium implantation and external irradiation. Jaffe et al. have shown, however, that some of the patients with cured carcinoma die later on with fibrosis of the ureter.

CLINICAL DIAGNOSIS

Carcinoma of cervix, with involvement of the bladder, ureters and rectum.

DR. CHUTE'S DIAGNOSES

Carcinoma of the cervix, with extension to the bladder and occlusion of the ureters.

Hydronephrosis bilateral.

Hydroureter, bilateral.

ANATOMICAL DIAGNOSES

Carcinoma of cervical stump, involving the bladder, and obstructing the ureters, with metastases to the right kidney and both lungs.

Vesicovaginal fistula.

Bilateral hydronephrosis, severe on right, slight on left.

Radiation fibrosis.

Septic pulmonary infarcts, multiple.

Old postoperative supravaginal hysterectomy.

Phleboliths.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Dr. Chute has outlined the problem very clearly; it concerned not the underlying disease but the nature of the terminal complications. At autopsy recurrent tumor was found occupying most of the pelvis. This had grown into the bladder and also into the vagina, and one complication which was not foreshadowed clearly by the symptoms was a vesicovaginal fistula. Perhaps the actual perforation did not occur until the patient had become virtually anuric, and for that reason it was not obvious. The lower ends of both ureters were completely surrounded and invaded by tumor. It was impossible to probe them from below, although working from above the probe could be forced through with considerable difficulty. The ureters above the point of

*Jaffe, H. L., Meigs, J. V., Graves, R. C. and Kickham, C. J. E. Ureteral and renal complications of carcinoma of cervix; their classification and management. *Surg., Gynec. & Obst.* 70:178-184, 1940.

obstruction were quite markedly dilated, and when a nick was made into them, urine under tension spurting out. Both kidneys showed a slight dilatation of the pelvis. The right kidney was normal in size. The left kidney weighed only 75 gm., which is more than an ordinary anatomic variation and probably means a considerable atrophy. I should therefore imagine that the obstruction had developed sooner on the left than on the right. The terminal pulmonary complication was one of multiple septic infarcts. There were also, however, a certain number of nodules of tumor in the lungs.

A PHYSICIAN: Was the mucous membrane of the rectum involved?

DR. MALLORY: No; we found no mechanical explanation for the obstipation. There were numerous adhesions within the abdomen, and one loop of ileum was firmly adherent to the dome of the bladder, a rather common complication in some of these heavily irradiated cases. The mucosa was normal and showed no signs of irradiation necrosis. There was another adhesion to the old laparotomy scar, but no kinking about either lesion. I do not believe that the patient had any actual obstruction.

ILL FARES THE LAND

CURRENT events have at last made it apparent, by the very monotony of their repetition, that in this century it is impossible for a nation to live within itself like a walled town, shut away from the outer world. The nation that tries to escape from the reality outside finds that reality comes and pounds on its gates. We are ourselves finally facing this fact, but only within a very few months have we come definitely to admit it.

The questions for which we have had to find the answers have been whether security can be bought with money or by success in barter and trade, or whether it can be purchased by the reactionary policies of appeasement. History has not only answered these questions for us in the negative, but has actually given us every reason to

doubt whether the average human being has ever had any reason to consider personal security a normal condition of life.

A great deal has been said about security in the last few years. The favored classes of this nation took economic security for granted in the lush years before 1917, and all classes anticipated it during the years of the inverted pyramid prior to 1929. After the financial debacle, it was one desideratum of living: a peaceful, strifeless security with a tight roof, oil heat, a radio by the fireplace and a policeman on the corner to keep away evil-doers.

The trouble with this security, as we are learning now, is its vulnerability. It is too dependent on peace on earth to men of good will. Everything must run smoothly to make it effective. Too many disturbances can take place to interfere with its serenity, and the only protection against them is to be equipped to handle them. When there are wolves around, the armed hunter, despite the risks of the chase, is more secure than the peaceful shepherd with his flock.

Security, of an individual or of a nation, is not a passive condition. It is the reward only of an alert, aggressive attitude, and when that spirit of aggressiveness falters and fades away, no sense of security can survive it for very long. The final protection against highwaymen does not lie in fast coach horses for escape, or in paying tribute to them, but in seizing them and dealing with them, with justice, but without mercy.

Security without effort, for the individual or the nation, is transitory and ephemeral. It is as undesirable as it is unreal. We have given ourselves over too much to the thought of security as being part of the natural condition of living. We have emphasized its importance in the life of the child. We have associated it with protective tariffs, high interest rates and iron-bound annuities, not realizing that we had completely missed its definition; it is not the accompaniment of an arrived millennium, but the reward of valor, of strength and of watchfulness.

Democracy with its institutions has of all forms of government come the closest so far to offering any material number of the earth's inhabitants the

opportunity to achieve and perhaps maintain a degree of security, but we are learning again that it is at the price of eternal vigilance. We may desire the perpetuation of what we consider certain fundamental rights of man, but they are recognized as rights only in a democracy, and we have to be willing to go forth in the defense of them. We have to risk in order to hold; we must sometimes lose in order to gain.

THE PREVENTION OF TETANUS

TETANUS does not rank high as a cause of death or of illness in ordinary times in New England, and its occasional occurrence has been regarded as more or less inevitable. This point of view is changing, and it seems possible that many cases can be prevented by prophylactic active immunization with tetanus toxoid.

Tetanus toxoid, prepared and administered in much the same way as diphtheria toxoid, produces a basic immunity and puts the specific protective mechanism of the body into such shape that it will respond rapidly when needed. In the event of subsequent injury, another injection of tetanus toxoid is followed by a rise in the patient's antitoxin titer high enough to prevent a tetanus infection. Should this injection be omitted through neglect of an apparently trifling injury, and should tetanus infection occur, the latter of itself may start the production of enough antitoxin to promote recovery or even prevent a clinically evident intoxication. Such at least is the rationale of active immunization against tetanus, and its theoretical basis is sound.

Experimental proof for this theory, at least so far as human beings are concerned, was not available until the current war produced injuries in quantity. Available data for the French army, where immunization was compulsory, and for the British army, where it has been extensively used, indicate that tetanus has been completely prevented in immunized persons. Most, if not all, of the credit for this has been ascribed to the use of toxoid.

Prophylactic administration of tetanus antitoxin, with the attendant serum reactions and sensitiza-

tion to serum, appears to be unnecessary in persons who have been actively immunized with toxoid.

The desirability of active immunization of troops seems beyond reasonable doubt. What of its use in civilian practice? Certainly those persons running more than the usual risk of exposure might well be immunized. In this group are veterinarians, hostlers, horsemen in general and farmers. Possibly children should also be placed in this category, for their risk of traumatic injuries is high. Persons already sensitive to horse serum might well consider immunization, to avoid the chance of allergic reactions following prophylactic doses of antitoxin. If the incidence of tetanus has been high in the civilian war-wounded, immunization of the general population should be considered in areas that are potential zones of attack.

The choice of an immunizing agent is still unsettled. Both fluid and alum-precipitated preparations have their advocates, and there are some advantages—without apparent disadvantages—in employing tetanus toxoid combined with diphtheria toxoid or typhoid vaccine. Reactions to tetanus toxoid are, on the whole, infrequent and mild; and their occurrence should tend to lessen as experience in manufacture and administration is increased.

Because of the present small number of cases and the cost of wholesale immunization, the prevention of tetanus with toxoid does not appear to be a problem to be dealt with by public-health officials. Practicing physicians, however, should advocate immunization, particularly for the groups mentioned above.

MEDICAL EPONYM

HENOCH'S PURPURA

Professor Eduard Heinrich Henoch (1820-1910) discussed "Ueber eine eigenthümliche Form von Purpura [A Peculiar Form of Purpura]" before the Berlin Medical Society on November 18, 1874. His paper appeared in the *Berliner klinische Wochenschrift* (11: 641-643, 1874). He had reported a single case six years previously. A portion of the translation follows:

The characteristic feature is the combination of purpura with marked intestinal symptoms. The latter manifest themselves in the form of colic, abdominal tenderness, vomiting (frequently of masses of green material) and bloody evacuations. Further, there were rheumatoid pains in all our cases, except one, including swelling of the joints in one case. Characteristic, too, was the occurrence of these symptoms in recurrent attacks at intervals of a week or more so that in the average case three to seven weeks elapsed, and in one case more than three months, before the final end of the process.

MASSACHUSETTS MEDICAL SOCIETY

PROPOSED CHANGES IN THE BY-LAWS

Through an oversight, the following proposed changes in the by-laws, which were approved by the Council at its meeting held on February 5, 1941, and were published in the February 27, 1941, issue of the *Journal*, were omitted from the list of proposed changes enclosed with the preliminary program recently forwarded to all members of the Society. A notice to this effect has been forwarded to each member, and a leaflet containing the additional changes will be distributed at the annual meeting of the Society.

AMENDMENT 16. Amend the first paragraph of Chapter IV, Section 1, to read:

The Council shall consist of councilors chosen by the district societies, and the president, ex-presidents, president-elect, vice-president, vice-presidents *ex officio*, secretary and treasurer of the general society, secretaries of the district societies, and the chairman of each standing committee.

AMENDMENT 17. Amend the first paragraph of Chapter IV, Section 3 to read:

The Council at its annual meeting, on nomination by the Nominating Committee and/or from the floor, shall elect by ballot officers of the Society as follows: president-elect, who shall serve as president-elect until the annual meeting of the Society next ensuing after his election and shall become president on his installation in the course of that meeting, serving thereafter as president until the next following annual meeting and the installation of his successor; a vice-president, secretary and treasurer, all of whom shall assume the duties of office at the close of the annual meeting of the Society and shall hold office until their successors have been duly elected; except only that at the annual meeting of the Society in 1941 there shall be nominated and elected a president to serve for that year.

In the absence of a president-elect, the Council, at its next annual meeting, shall upon nomination by the Nominating Committee and/or from the floor, elect a president. Councilors only shall be eligible to the offices above named. Upon nomination by the Nominating Committee, the Council shall elect by ballot a fellow to deliver an oration at the annual meeting of the Society the following year.

AMENDMENT 18. Change Chapter VI, Section 3, to read:

The President-Elect shall assist the President in the performance of his duties in such a manner as the President may direct and in so doing shall be considered to represent the President.

AMENDMENT 19. Change Sections 3, 4 and 5, Chapter VI to Sections 4, 5 and 7, respectively.

ROBERT N. NYE, *Secretary pro tempore*.

COMMITTEE ON STATE AND NATIONAL LEGISLATION

House Bill 1222, the bill to establish a separate board of registration for chiropractors was given "leave to withdraw" by the Committee on Public Health on April 15; this report was accepted by the House the next day, but will have to be accepted by the Senate, before it is finally disposed of.

HENRY C. MARBLE, *Chairman*.

SECTION OF OBSTETRICS AND GYNECOLOGY*

Boston

DEATH FOLLOWING MISMANAGEMENT OF DELIVERY

A thirty-four-year-old primipara who had received no prenatal care was sent to a state institution about a week before her expected date of delivery.

The past history was entirely irrelevant. She had never had scarlet fever or kidney trouble.

Physical examination on admission was normal. The heart was not enlarged; there were no murmurs. The lungs were clear and resonant; there were no rales. The blood pressure was 130 systolic, 80 diastolic. The abdomen was the size of a full-term pregnancy, and the fetal heart was heard. There was considerable edema of both legs. The urine showed a large amount of albumin. There was no record of the patient's weight. She was put to bed and treated for mild toxemia.

Six days after entrance, labor started spontaneously. It was said that at the end of twelve hours the cervix was fully dilated. The position was a posterior vertex, and the head was thought to be in the mid-pelvis. Under ether anesthesia a high-forceps delivery was attempted, without success; another physician attempted version, which likewise failed. Following these two operative procedures, a third consultant was called to decide

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

whether a cesarean section should be performed. This was decided against because the patient was in such poor condition. She died a few hours later, undelivered.

Comment. No comment is really necessary. Although this patient had no prenatal care, her death cannot be attributed to her own neglect. There is no excuse for such obstetrics. It is only fair to say that no obstetrician saw this patient. Until the obstetrics that is done in all hospitals, including state as well as private and incorporated institutions, is adequately supervised, an occasional repetition of this disaster is unavoidable.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 27.

Bristol South (Fall River Section)

Tuesday, April 29, at 4 30 p.m., at the Union Hospital, Fall River. Pediatric Case Discussions. Instructor R. Cannon Eley. Howard P. Sawyer, *Chairman*.

Hampden

Wednesday, April 30, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Recent Advances in Medical Therapeutics. Instructor Charles L. Short. Alfonso A. Palermo, *Chairman*.

Worcester

Tuesday, April 29, at 8 30 p.m., in the Nurses' Home of the Milford Hospital, Milford. Infections of the Hands and Feet. Instructor William E. Browne. Joseph Ashkins, *Chairman*.

APPLICANTS FOR FELLOWSHIP

Owing to an error, the following names were omitted from the list of applicants for fellowship printed in the April 10 issue of the *Journal*.

Hampden District

McEllicott, Maurice James, Westfield State Sanatorium, Westfield.
Rush Medical College, University of Chicago, 1937.
Wayne C. Barnes, *Secretary*.

Plymouth District

Golstein, Walter, 169 West Elm Street, Brockton.
University of Berlin, 1923.
Mathews Molyneux Paul, 28 Maple Avenue, Brockton.
Middlesex University School of Medicine, 1933.
Ralph C. McLeod, *Secretary*.

DEATHS

McCarthy—Thomas H. McCarthy, M.D., of Brockton, died April 11. He was in his seventy eighth year.

Dr. McCarthy received his degree from the Harvard Medical School in 1890. He was on the surgical staff of the Brockton Hospital at the time of his death. He held memberships in the Massachusetts Medical Society and the American Medical Association.

Packard—Loring B. Packard, M.D., of Brockton, died April 12. He was in his sixty fifth year.

Born in Sharon, he attended Yale University and received his degree from Harvard Medical School in 1903. After two years at the Boston City Hospital, he became resident surgeon at the Haymarket Relief Station, Boston. In 1912 he became superintendent of the Brockton Hospital, which capacity he filled until his retirement in 1919. At the time of his death he was on the staff of the Brockton Hospital as surgeon and roentgenologist.

Dr. Packard was a member of the Massachusetts Medical Society, the American Medical Association and the New England Roentgen Ray Society.

MISCELLANY

MAINE NEWS

MAINE MEDICAL ASSOCIATION

The annual meeting of the Maine Medical Association will be held at the Marshall House, York Harbor, on June 22, 23 and 24.

The following physicians have been recently admitted to membership in the Maine Medical Association.

Everett F. Conlogue, Fairfield.
Paul A. Jones, Union.
William B. O'Sullivan, Biddeford.
L. Dean Webber, Kittery.

THAYER HOSPITAL, WATERTOWN

Staff meetings are held at the Thayer Hospital, Watertown, at 7 30 p.m., on the first second and fourth Thursdays of every month from September to May, inclusive (the Kennebec County Medical Association meets on the third Thursday of every month). In addition to clinical case studies, panel discussions and guest speakers are included in certain of the programs. Dr. Arnold P. Meiklejohn, of the Thorndike Memorial Laboratory, Boston City Hospital, will speak on "Vitamin Therapy" at the May 1 meeting. Dr. Samuel A. Levine, of Boston, will speak on "Some Important Errors in Cardiac Diagnosis" at the May 22 meeting. The profession is cordially invited to attend these meetings.

PANEL DISCUSSIONS

The following panel discussions, with the names of the chairmen, are available to the county medical societies in 1941.

Coronary Disease. Dr. E. H. Drake, Portland.
Complications of Pregnancy. Dr. R. B. Moore, Portland.
Diseases of the Liver and Bile Passages. Dr. J. Gottlieb, Lewiston.
Endocrine Dysfunction. Dr. J. Carswell, Camden.
Syphilis. Dr. O. R. Johnson, Portland.
Chemotherapy. Dr. F. T. Hill, Waterville.
Appendicitis. Dr. I. M. Webber, Portland.

NOTICES

BOSTON MEDICAL HISTORY CLUB

The next meeting of the Boston Medical History Club will take place at the Boston Medical Library, 8 Fenway, Boston, on Monday, April 28, at 8:15 p.m. Dr. Iago Galdston, secretary, Medical Information Bureau, New York Academy of Medicine, will speak on "Humanism and Public Health."

All interested persons are cordially invited to attend.

HENRY JACKSON LECTURE

The Henry Jackson Lecture for 1941, under the auspices of the New England Heart Association, will be given on Friday, May 2, at the Boston Medical Library at 8:15 p.m. Commander J. R. Poppen, M.D., Navy Department, Bureau of Aeronautics, Washington, D. C., will discuss "Cardiovascular Problems in Aviation Medicine."

Interested physicians and medical students are cordially invited to attend.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM, MAY

Thursday, May 1—Epidemiologic Field Trip to Halifax.
Dr. J. H. Dingle.

Friday, May 2—Pancreatic Disease and Enzyme Analysis in Early Life. Drs. Sidney Farber and Charlotte Maddock.

Tuesday, May 6—Pneumoencephalography. Dr. Kurt Goldstein.

Wednesday, May 7—Urticaria. Dr. E. A. Brown.

Thursday, May 8—Hospital case presentation. Dr. S. J. Thannhauser.

Friday, May 9—Marked Hyperthyroidism. Dr. Oliver Cope.

Tuesday, May 13—Subacute Bacterial Endocarditis with Special Reference to Treatment. Dr. J. M. Faulkner.

Thursday, May 15—Some of the Effects of Flying on the Cardiovascular System. Dr. Ashton Graybiel.

Friday, May 16—Early Diagnosis of Carcinoma of the Stomach. Dr. B. B. Crohn.

Tuesday, May 20—Clinicopathological conference. Drs. C. S. Keefer and H. E. MacMahon.

Thursday, May 22—Extrarenal Azotemia. Dr. Emanuel Ginsburg.

Friday, May 23—Some Current Problems in Gastrointestinal Surgery. Dr. Richard Warren.

Tuesday, May 27—Secretin Test of Pancreatic Function. Dr. A. S. Hartwell.

Thursday, May 29—X-ray demonstration. Dr. Alice Ettinger.

On Wednesday and Saturday mornings throughout the month, with the exception of May 7, Dr. S. J. Thannhauser will give a medical clinic on hospital patients.

SUFFOLK DISTRICT MEDICAL SOCIETY

The annual meeting of the Suffolk District Medical Society will take place on Wednesday, April 30, at 8:15 p.m., at the Boston Medical Library.

PROGRAM

Short History of Eclampsia. Dr. Robert M. Green.
Symposium on Pre-eclamptic Toxemia and Eclampsia.
Drs. Burton E. Hamilton, Arthur T. Hertig, Maurice B. Strauss, George van S. Smith, Duncan E.

Reid, George C. Prather and Raymond S. T. (chairman).

There will be a business meeting at 8:00 p.m. for election of officers and the report of the society for 1940.

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The spring meeting of the New England Obstetrical and Gynecological Society will be held in Providence, Rhode Island, on Wednesday, May 14. Registration will be held at the Providence Lying-In Hospital, 50 Main Street, Providence. Two programs will run concurrently in the morning: one beginning at 9:00 at the Providence Lying-In Hospital and consisting of inspection of hospital and a dry clinic; the other at the Rhode Island Hospital beginning at 8:00 with an operative clinic followed by a symposium on cancer and a dry clinic. Luncheon at 12:30 will be served at the two hospitals.

The afternoon program will commence at 1:30 at Providence Lying-In Hospital, with a meeting of executive committee, a symposium on hydatidiform mole and chorioepithelioma, and the presentation of papers. The general meeting of the society will follow at 4:15, with a reception and dinner at the Squantum Club at 5:30.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

The annual meeting of the Middlesex South District Medical Society will be held at the Hotel Continental, Cambridge, on Wednesday, May 14.

PROGRAM

11:30 a.m. Business meeting.
12 m. Annual Oration: Middlesex South and Massachusetts medicine. Dr. Harold G. Giddings.
12:45 p.m. Luncheon.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	CLINIC CONSULTANT
Lowell	May 2	Albert H. Brewster
Haverhill	May 7	William T. Green
Brockton	May 8	George H. Van Gorden
Gardner	May 13	Mark H. Rogers
Worcester	May 16	John W. O'Meara
Pittsfield	May 19	Frank A. Slowick
Northampton	May 21	Garry deN. Hough, Jr.
Fall River	May 26	Eugene A. McCarthy
Hyannis	May 27	Paul L. Norton

HAMPDEN DISTRICT MEDICAL SOCIETY

The annual meeting of the Hampden District Medical Society will be held on Tuesday, April 29, at Hotel Federal, Springfield, at 4:00 p.m. Dr. H. Edward MacMahon, professor of pathology, Tufts College Medical School, will speak on "Clinical and Morphologic Findings in Bright Disease." Dinner will be served at 6:30 p.m. at the expense of the society.

ANNUAL CONCERT OF THE BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will give its second annual concert on Sunday, May 11, at 8:15 p.m.

in Jordan Hall Alexander Thiede will conduct Dr. Werner Mueller will appear as soloist.

Proceeds of the concert will be used for the establishment of a fund for a free bed in each of the following hospitals: Beth Israel Hospital, Children's Hospital, Massachusetts Eye and Ear Infirmary and Boston Dispensary. Tickets at \$1.00 may be obtained by applying to Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The next annual meeting of the American Association for the Study of Goiter will be held at the Hotel Statler, Boston, on May 12, 13 and 14. The program for the three-day meeting will consist of papers dealing with goiter and other diseases of the thyroid gland, dry clinics and demonstrations.

POSTGRADUATE COURSE IN OBSTETRICS

The Illinois State Department of Public Health and the Children's Bureau, United States Department of Labor, are sponsoring ten 4 week courses in obstetrics at the Chicago Lying in Hospital during the fiscal year 1941-1942. Only a limited number of physicians will be accepted for each course. The only cost to those taking the course is for room and board and \$25.00 (\$10.00 of which is refunded at the completion of the course). Applications and inquiries should be addressed to Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue, Chicago, Illinois.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 27

MONDAY, APRIL 28

- 12:15-1:15 p.m. Clinicopathological conference Peter Bent Brigham Hospital amphitheater

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Techniques of Conception Control By Robert Latou Dickinson, M.D., and Woodbridge Edwards Morris, M.D., general medical director, Birth Control Federation of America. A practical manual issued by the Birth Control Federation of America, Incorporated. 4", paper, 56 pp., with 50 illustrations and 3 tables. Baltimore: Wilkins and Wilkins Company, 1941. 50c

Atlas of Electroencephalography. By Frederic A. Gibbs, M.D.; and Erna L. Gibbs. F°, cloth, 221 pp., with 18 figures and 102 plates. Cambridge, Massachusetts: Lew A. Cummings, 1941. \$7.00.

Merchants in Medicine. By Emanuel M. Josephson, M.D. 8°, paper, 23 pp. New York: Chedney Press, 1941. \$1.50.

A Diabetic Manual: For the mutual use of doctor and patient. By Elliott P. Joslin, M.D., ScD., clinical professor of medicine emeritus, Harvard Medical School, medical director, George F. Baker Clinic, New England Deaconess Hospital, and consulting physician, Boston City Hospital. Seventh edition, thoroughly revised. 8°, cloth, 238 pp., with 53 illustrations and 24 tables. \$2.00.

Natural Resistance and Clinical Medicine. By David Perla, M.D., instructor in medicine, Columbia University College of Physicians and Surgeons; and Jessie Marmors-ton, M.D., assistant in pathology, Cornell University Medical College. 4°, cloth, 1344 pp., with 44 tables. Boston: Little, Brown and Company, 1941. \$10.00.

That None Should Die. By Frank G. Slaughter, M.D. 8°, cloth, 423 pp. New York: Doubleday, Doran and Company, Incorporated, 1941. \$2.75.

Applied Physiology. By Samson Wright, M.D., F.R.C.P., John Astor Professor of Physiology, University of London Middlesex Hospital Medical School, and examiner in physiology, University of Leeds. Seventh edition. 8°, cloth, 787 pp., with 367 illustrations. New York: Oxford University Press, 1940. \$7.00.

The Medical Clinics of North America. Vol. 25, Number 2. March, 1941: Baltimore Number. 8°, cloth, 303 pp., with 21 illustrations and 9 tables. Philadelphia: W. B. Saunders Company, 1941. \$2.67.

Studies from The Rockefeller Institute for Medical Research. Reprints, Vol. 117. 4°, paper, 606 pp., with 127 tables and 128 illustrations. New York: The Rockefeller Institute for Medical Research, 1941. \$2.00.

Science and Seizures: New light on epilepsy and migraine. By William Gordon Lennox, M.D., ScD. (hon.), assistant professor of neurology, Harvard Medical School, and visiting neurologist, Boston City Hospital. 8°, cloth, 258 pp., with 10 illustrations. New York: Harper and Brothers, 1941. \$2.00.

BOOK REVIEWS

A Textbook of Medicine. Edited by Russell L. Cecil, M.D., ScD. Fifth edition, revised and entirely reset. 8°, cloth, 1744 pp., with 173 illustrations. Philadelphia and London: W. B. Saunders Company, 1940. \$9.50.

When a textbook of medicine reaches its fifth edition it is fair to assume that its worth is established and that it may take rank with the best in American medical literature. This treatise is a summary of present-day medicine by one hundred and thirty-five American authors, each one an authority in his field. That so many participate in this work is due to the fact, in the words of the editor, "that the rapid growth of medical science during the last few years has made it almost impossible for a single individual to master the entire field." It is a fine demonstration of the high standard of internal medicine in America. Still one misses the personality of the individual master that is found in works like Osler's *Practice of Medicine*.

Introduction to Medical Biometry and Statistics. By Raymond Pearl, Sc.D., Ph.D., LL.D. Third edition, revised and enlarged. 8°, cloth, 537 pp., with 121 illustrations, and 140 tables. Philadelphia and London: W. B. Saunders Company, 1940. \$7.00.

Statisticians are familiar with the early editions of this work and will welcome this new one, which is a great improvement. For this group the volume is of great value—the chapter on sampling is a masterpiece. The preface gives the impression that the book is for beginners in this field of medicine, but actually it is too advanced for novices. The late Dr. Pearl states that he has omitted "accounts of many of the recent and more rec-ondite mathematical developments of statistical methodology," but he has included too many advanced methods for the physician attempting to obtain a rudimentary knowledge of the subject. Throughout the book are parts that would be exactly what the physician needs, and interspersed are far too advanced ideas. However, no ideal treatment of this subject is available to the physician, and this volume seems the nearest approach. The book could be of great value for the practitioner attempting statistical analysis, if he had the advice of someone with experience in the statistical field in selecting such parts of the book as he should study.

The Virus: Life's enemy. By Kenneth M. Smith, F.R.S. 12°, cloth, 176 pp., with 19 illustrations. New York: Macmillan Company, 1940. \$2.00.

The inability to obtain a visual image of the virus long delayed a direct approach to the study of these substances. However, methods were evolved that obviated many of the difficulties, and new vistas have been opened to an understanding of the nature and action of the virus. The author presents an able and concise summary of the fruits of virus research. This should prove an excellent introduction to those who are not in a position to delve into the extensive literature pertaining to these agents, a literature that embraces chemistry and botany as well as epidemiology.

That the two great enigmas of medicine, neoplasms and viruses, may be related is, indeed, intriguing, and data here presented point in that direction. Preoccupied as one may be with the chemotherapeutic achievements recently gained, one must not lose sight of the great importance of the role of the virus disease in man and his environment.

The Histamine and Insulin Treatment of Schizophrenia and Other Mental Diseases. By Horace Hill, M.R.C.P. 12°, cloth, 133 pp. Baltimore: Williams and Wilkins Company, 1940. \$1.75.

Of the various types of shock treatment used for schizophrenia, insulin has had the widest use up to recent times. Hill has added histamine to the insulin treatment and believes that the results are better than with insulin alone. In this small book, he gives case reports of 34 patients treated by this method; 12 were considered well at the end of the course of treatment, and 12 others were improved. Most of the patients suffered from schizophrenia, but a number showed signs of involutional melancholia. A detailed report on all the cases is given as an appendix to this brief monograph, and there are various references to the literature. Although this method of treatment has been largely superseded by other methods, Hill's reports will be found of interest to psychiatrists.

REDUCTION OF PAIN AND OTHER UNDESIRABLE REACTIONS DUE TO PNEUMOENCEPHALOGRAPHY*

THEODORE J. C. VON STORCH, M.D.,† AND HOWARD H. KARR, M.D.‡

BOSTON

SINCE its introduction by Dandy¹ twenty years ago, pneumoencephalography has become an accepted diagnostic procedure in the practice of neurology, neurosurgery and psychiatry. When properly performed, it results in a mortality of less than 0.3 per cent.²⁻⁴ The indications for encephalography are numerous, the contraindications few.^{2,3,6-11} Unfortunately, encephalography is an extremely painful procedure. When pain no longer functions as a defense mechanism, it becomes a pathologic process, the existence of which is unjustifiable. Furthermore, continued pain during encephalography causes marked fluctuations in respiration and intravascular pressure, and is, perhaps, productive of shock. Other accessory reactions to encephalography are hyperthermia, nausea, vomiting, aseptic meningitis and, occasionally, urinary retention and shock. Physicians who fail to follow the postencephalographic course of their patients are too often unimpressed by the necessity of reducing the subsequent reactions. Others are overly impressed and hesitate to utilize this valuable diagnostic method. Various means have been used to diminish the undesirable reactions of encephalography. It is our purpose to analyze these methods and to draw therefrom certain conclusions, which eight years' experience has shown to be of practical value.

CONTRAINDICATIONS AND PRECAUTIONS

Tumor of the posterior fossa and evidence of marked increased intracranial pressure are contraindications to encephalography. Patients with advanced hydrocephalus do not do well, as a rule. In such cases, especially in children, it is necessary

to force fluids after the procedure, to replace the relatively large volume of fluid that has been lost. Difficulties may be encountered when marked cerebral arteriosclerosis is present. Hemorrhage may be met with in marked arterial hypertension or in thin-walled intracranial aneurysms. In general, cases with brain tumor react more severely than those without tumor. Nevertheless, when proper precautions are taken, encephalography may be safely performed in any of these conditions except tumor of the posterior fossa or marked increase in intracranial pressure.

PRE-ENCEPHALOGRAPHIC CONSIDERATIONS

When apprehension is a significant factor it may be diminished by the oral administration of from 1½ to 3 gr. of Nembutal (sodium ethylmethylbutylbarbiturate, Sodium Amytal (sodium isoamylethylbarbiturate) or another suitable sedative on the night before encephalography.^{2,6,12,13} A repetition of the same dose of sedative about two hours before the procedure is occasionally necessary. To avoid the untoward results of vomiting, the previous meal should be omitted and fluids limited. Vomiting can be prevented in most cases by the subcutaneous injection of from 1/150 to 1/50 gr. of atropine sulfate, one hour before lumbar puncture. The use of the larger dose, in adults, diminishes any tendency toward laryngeal spasm, which may occur when the nonvolatile intravenous anesthetics are employed. Atropin also decreases nasopharyngeal and oral secretions, which may complicate the use of any anesthetic.

ENCEPHALOGRAPHIC CONSIDERATIONS

In co-operative subjects, lumbar puncture after local novocain infiltration is usually less difficult than in relaxed anesthetized subjects. With unco-operative subjects it is advisable to induce anesthesia before attempting the puncture.

*From the Evans Memorial, Department of Clinical Research and Preventive Medicine, Massachusetts Memorial Hospitals, the Department of Medicine, Boston University School of Medicine; the Department of Neurology, Harvard Medical School, and the Neurological Service, Boston City Hospital.

†Assistant professor of neurology, Boston University School of Medicine; physician, Evans Memorial; instructor in neurology, Harvard Medical School, and assistant visiting neurologist, Boston City Hospital.

‡Neurosurgical resident, Boston City Hospital.

Analgesia

Morphine,^{2, 14} scopolamine,^{11, 13, 15, 16} chloral hydrate,^{8, 9, 12} oral Nembutal,⁶ and Amytal^{4, 7, 17} have been recommended as analgesic agents. Partial analgesia or narcosis is easier to obtain than complete anesthesia, and the patient requires less attention. On the other hand, it produces an incompletely relaxed patient, who is not infrequently unco-operative. The patient still suffers unnecessary pain and often requires further analgesia or the use of aromatic spirits of ammonia.^{2, 8} Epileptic and psychotic patients often become unmanageable under barbiturates. Morphine causes an additional respiratory strain, and is indicated only when barbiturates cannot be used. Therefore, it is our opinion that general anesthesia is preferable to partial analgesia.

Anesthesia

General anesthesia entirely relieves the pain of encephalography, contributes largely to its prevention in the postencephalographic period, prevents undue haste due to the patient's repeated complaints, and prevents struggling that tends to cause intracranial hemorrhage or to dislodge the drainage needles. On the other hand, accidents may occur if the operator is unfamiliar with the use of the anesthetic employed. Some type of support is necessary because of the relaxation of the patient—several such supports have been described.^{12, 18-21} The constant attention of the anesthetist is necessary for the proper induction and maintenance of the anesthesia, especially when the intravenous route is used. Nevertheless, the advantages may be said to outweigh the disadvantages. However, the choice of anesthetic is of great importance in obtaining satisfactory results.

Inhalation anesthesia. Ether,^{3, 22-25} ethyl chloride²⁶ and nitrous oxide²⁷ have been recommended for inhalation anesthesia. All these gases increase arterial, venous and cerebrospinal-fluid pressures to a marked degree and in a fluctuant fashion. These increases interfere with any simultaneous-replacement method, prevent the use of automatic methods¹³ and predispose to intracranial hemorrhage, cerebral edema and herniation of the medulla. Vomiting is not infrequent, and respiratory complications may occur. A constant level of anesthesia is difficult to maintain, and the postencephalographic period is apt to be stormy. For these reasons, it is advisable to use inhalation anesthetics in encephalography only as a brief induction to other analgesic methods.²²

Rectal anesthesia. Avertin (tribromethanol in amylene hydrate) has been recommended for this purpose.^{25, 28, 29} After instillation, the oper-

ator has very little control over the depth of anesthesia. Therefore, the tendency is to give too little, with the result that the patient emerges before completion of encephalography, making necessary to use supplementary inhalation anesthesia. Emergence usually occurs just as roentgenography is attempted, with the result that the films are spoiled by movement of the patient. Furthermore, because the patient is in the sitting position, the anesthetic fluid is often expelled during the encephalographic procedure. For these reasons, and others enumerated by Sise,³⁰ most clinics have justifiably abandoned the use of rectal anesthesia for encephalography, except in children in whom intravenous anesthesia may be impractical or dangerous.

Intravenous anesthesia. This method has been used, in recent years, with increasing frequency. Sodium Amytal,^{14, 28} Nembutal,^{13, 28, 29} Evipal Sodium (sodium methylcyclohexenylmethylbarbiturate)^{29, 31, 32} and paraldehyde^{33, 34} have been used. In the last few years, several clinics have used Pentothal Sodium (sodium ethylmethylbutylthiobarbiturate) extensively. Our experience with the last drug has led us to believe that, with proper precautions, it is the best available anesthetic for pneumoencephalography, and we are in complete accord with Nicholson and Sise,³² who have recently reported excellent results in 177 cases. Contraindications to its use include any condition that may encroach on the airways, gross hepatic disease, severe anemia, severe renal disease, extreme debility and cardiac decompensation. These, however, are contraindications to encephalography itself. Although not recommended in children under seven years of age, it has been used successfully in an occasional case. Rectal Avertin is preferable in patients under seven. In persons with low blood pressure, the introduction of gas into the cranium is usually sufficient to re-elevate the pressure. Respiratory depression or laryngeal spasm occasionally occurs. Preoperative administration of from 1/150 to 1/50 gr. of atropine sulfate is effective in preventing laryngeal spasm. Infrequently, it is necessary to keep the airways open by catheterization. Ten per cent carbon dioxide with oxygen should be kept at hand but rarely needs to be utilized. One or two cubic centimeters of 25 per cent Coramine (pyridine-beta-carboxylic acid diethylamide) intravenously will rapidly counteract the effects of Pentothal Sodium, if necessary. In our experience the most important factor in the use of Pentothal Sodium is the maintenance of a slow, almost continuous, intravenous administration. Untoward results are rare, and are almost invariably due to rapid injection. A dangerous dose of these

drugs is dependent not so much on the total amount as on the rate of injection.²⁰

The following method is recommended:

From one to one and a half hours after administration of 1/150 to 1/50 gr. of atropine sulfate, the patient is placed erect in the chair for cephalography. Several arterial pressure determinations are made, the elbow is splinted in extension and venipuncture is performed at the brachial vein. A 5 per cent solution of Pentothal Sodium in sterile normal saline solution is then slowly introduced by almost imperceptible movement of the plunger of a 20-cc. syringe. The rate is maintained or lessened according to the depth of anesthesia. Injection is continued during the replacement of cerebrospinal fluid, and the needle withdrawn just before roentgenography. Observations are occasionally made of the arterial tension, and the mouth and neck are watched to prevent airway obstruction.

This method results in a pleasant induction and a uniform maintenance of a relaxed anesthetic state. Complete relaxation is obtained during the subsequent roentgenography, which immediately follows replacement of the cerebrospinal fluid.²² No subsequent analgesia is needed for from four to twelve hours after the procedure. The cerebrospinal-fluid pressure is unaltered, and the arterial tension is apparently unaffected. Respiratory depression has been rare in our experience. Therefore, although the use of Evipal or paraldehyde deserves further consideration, at present Pentothal Sodium seems to be the most effective means of obtaining adequate anesthesia during pneumoencephalography.

Type of Gas Used

Filtered and unfiltered air, carbon dioxide, nitrogen and helium have been used to replace the cerebrospinal fluid.²⁵ Ethyl chloride, divinyl chloride, vinyl chloride, acetylene, cyclopropane and ether have been used in animals;²⁶ nitrous oxide and ethylene in human beings.²² Freon (dichlorodifluoromethane) has been used by one of us.²⁷ Many clinics use oxygen, but most continue to utilize room air. Of these gases, unfiltered room air is used most frequently but causes the severest reactions; filtered air causes some diminution of the reaction; helium and oxygen are said to be less irritating than air; nitrous oxide is better than oxygen, and according to the results in over 600 cases, ethylene is least irritant.²² The remaining gases are either too dangerous, or not sufficiently better than air, to warrant consideration.

Aird²² has used pure ethylene to replace the cerebrospinal fluid in over 600 cases, with excellent roentgenographic results and a marked decrease in the accessory effects of encephalography. Although ethylene is highly explosive when mixed with air, it is not explosive when maintained in the pure form in a closed system. There have

been no untoward results as yet from the use of this gas. The use of such an anesthetic gas does not, however, render anesthesia (Avertin fluid) unnecessary, although in children an induction anesthesia of ether is sufficient. The real value of ethylene is in reduction of postencephalographic reactions. Because of the fear of explosion, very few workers have used this method. Aird's results suggest that such fear may be unfounded.

It may be said that although, because of inertia and convenience, air continues to be the gas most frequently used in encephalography, other gases lessen the reactions afterward and diminish them somewhat during the procedure. Oxygen is preferable to air from this point of view, and if the fear of explosion can be overcome, ethylene is perhaps the gas of choice.*

Amount of Gas Used

The reaction to encephalography varies directly with the amount of gas used.^{2, 38} The use of small volumes in the so-called "ventricular repérage" results in a minimum of discomfort, some patients being up and about within several hours after injection.³⁹ On the other hand, injection of small amounts of air is in most cases inadequate for the diagnosis of more than the most obvious intracranial masses or gross ventricular enlargement.²³ After the introduction of 100 cc. of gas, additional replacement causes little change in the patient's immediate reactions. Additional gas does, however, prolong the subsequent discomfort. It may be said, therefore, that even though less gas diminishes the subject's reactions, it is necessary in all but a few cases to replace completely the cerebrospinal fluid with whatever amount of gas may be necessary.

Method of Cerebrospinal-Fluid Replacement

Numerous observations have demonstrated that the two-needle, simultaneous method of replacing cerebrospinal fluid by gas diminishes the patient's reactions during and subsequent to encephalography.^{23, 38} Several types of apparatus have been described that render replacement more or less automatic.^{12, 40-43} To avoid mechanical irritation of the brain, which, after replacement of cerebrospinal fluid, is lying in a "dry box," and to avoid undue tension on the meninges and on the vessels at the vertex, a minimum of manipulation should be maintained. Slow, continuous anteroflexion and posteroflexion of the head is sufficient for adequate ventricular replacement. Transportation

*It should be emphasized that when readily absorbable gases are used, such as oxygen or to a greater degree ethylene, the roentgenologic technique must be accelerated accordingly.

and handling of the patient should be at a minimum.

POSTENCEPHALOGRAPHIC CONSIDERATIONS

As has been noted, anesthesia with intravenous Pentothal Sodium diminishes the sequelae of encephalography. The use of ethylene to replace the cerebrospinal fluid exerts most of its effect in diminishing postencephalographic reactions. Avoidance of unnecessary cranial manipulation tends to decrease subsequent ill effects, and the use of the simultaneous-replacement method does likewise.

If shock occurs, the use of Coramine, caffeine sodium benzoate and warmth is usually sufficient therapy. It has been found unnecessary to elevate the foot of the bed. Only in rare cases has it been necessary to administer clysis to adults. In children, fluids are sometimes useful. In children with hydrocephalus, it is essential to administer fluids at once because of the dehydration that occurs when the body attempts to restore the relatively immense volume of cerebrospinal fluid that has been replaced by gas. In adults with hydrocephalus, fluids are helpful but not essential. Lumbar puncture after encephalography usually reveals a lowered rather than an increased intracranial pressure and is therefore of no value except in rare cases of increased pressure due to subsequent edema or hemorrhage.⁴⁴ In every case it is advisable to observe the temperature, respiration, arterial pressure, pulse pressure and pulse rate carefully for twenty-four hours after encephalography. A wet icecap is helpful if applied immediately on return to the ward. Codeine and acetyl salicylates may be given when necessary. Three grains of Nembutal by mouth is helpful. Morphine is to be avoided.

If the patient is allowed to breathe 95 per cent oxygen for two or three hours after encephalography, the intracranial gas is rapidly removed, and the subsequent course is greatly improved.⁴⁵ The oxygen can be more readily administered through a Boothby respirator mask than by the apparatus described by Schwab, Fine and Mixer.⁴⁶ Seven to eight liters of 100 per cent oxygen are delivered per minute.

After all reaction to encephalography has disappeared, the patient may complain of a postlumbar-puncture headache that occurs only in the erect position. This can be relieved by the intravenous injection of $7\frac{1}{2}$ gr. of caffeine sodium benzoate from one to three times a day or by the resumption of recumbency.

SUMMARY

So that pneumoencephalography may be available for use in all cases in which it promises to

be of value, every effort should be made to reduce the dangers, pain and other untoward reactions. This may be accomplished to a large degree by proper consideration of the contraindications to encephalography; the liberal use of preliminary sedation, for which Nembutal has been found most useful; prophylactic injection of from 1/150 to 1/50 gr. of atropine sulfate; the use of an effective intravenous anesthetic, such as Pentothal Sodium; the use of a suitable gas, such as air, oxygen or possibly ethylene; simultaneous replacement of the cerebrospinal fluid by gas; avoidance of undue manipulation of the patient; careful postencephalographic observation and the use of analgesics and sedatives, when necessary; the use of fluids and shock therapy, when indicated; and the inhalation of 95 per cent oxygen, when necessary.

THE ESTIMATION OF OPERATIVE RISK IN PATIENTS WITH CANCER*

ALLEN S. JOHNSON, MD,† AND HERBERT L. LOMBARD, MD‡

SPRINGFIELD AND BOSTON, MASSACHUSETTS

THE operative mortality in a hospital limited to the treatment of cancer is necessarily high, but a preliminary review of a few hundred cases gave the impression that a lower mortality could be obtained by limiting operations to selected patients without obesity, malnutrition, hypertension or a history suggesting cardiac disease. This study was undertaken to prove whether or not this thesis was correct. The material consisted of 2445 cases subjected to major operations at the Massachusetts state cancer hospitals at Pondville (1927 to 1939) and at Westfield (1937 to 1939).

Operative mortality is a term lacking in precise definition. In this study we have used the criteria of Warren,¹ who considered that patients dying within one month after operation were operative deaths, provided the death was not due to the natural course of the condition for which the operation was done. According to this definition, a patient dying of pneumonia or heart failure, obviously precipitated by the operation, is listed as an operative death. This is true of sepsis having a causal relation to the operative procedure. It has also seemed justifiable to list as an operative death an occasional patient who survived the arbitrary one month, but who pursued a progressively downhill course with one postoperative complication after another and finally died of the complications and not of the original disease that necessitated the operation. Because a patient who has developed fatal lung abscesses after resection of the rectum is still breathing, although moribund, thirty days later, it does not seem rea-

sonable to absolve the operation from responsibility for the death. On the other hand, patients were not so listed who, after a palliative operation, died of sepsis due to the original lesion and antedating the surgical procedure.

Although a variety of fatal lesions were often present at the time of death, some were listed by the pathologist as the "immediate cause of death" in the autopsied cases, which comprised 58.5 per cent of the fatalities. In the cases not subjected to autopsy it was necessary to rely on a careful appraisal of the data in the histories. For example, a patient with obvious sepsis was

TABLE 1 Operative Mortality Subdivided by the Age of the Patient

70 and over	368	85	23.1
Totals	2444*	386	

*In 1 case the age was unknown.

not listed as dying of heart failure just because his heart finally stopped beating. On the other hand, the classic clinical picture of congestive heart failure, although it might have been precipitated by postoperative sepsis, was listed as the cause of death if the patient succumbed under these circumstances. In the hope of eliminating inconsistencies resulting from appraisal by different people, one of us (A. S. J.) undertook the entire task of evaluating the clinical data, and the other (H. L. L.) assumed the responsibility for the statistical computations.

It is well recognized that increasing age produces an increase in surgical mortality. Table 1

*From the Cancer Section, Westfield State Sanatorium and the Pondville Hospital (Wrentham), Massachusetts Department of Public Health.

†Training physician, Westfield State Sanatorium.

‡Director, Division of Adult Hygiene, Massachusetts Department of Public Health.

shows the operative mortality according to age groups. Mortality increases progressively up to the age of sixty; from then on it is practically stationary.

A history of cardiac disability has been considered by many observers to increase operative risk. In this group were listed all patients who gave a history of exertion dyspnea, cyanosis, angina or edema that could be ascribed to heart disease. Dyspnea or cyanosis due obviously to a pulmonary lesion or edema due to hypoproteinemia or varicose veins was naturally excluded. The patient's history was given more consideration than the physical or laboratory examinations for two reasons. First, as Marvin² has emphasized, the history is more important than the physical examination in determining the patient's ability to withstand anesthesia and operation; and Sprague³ has pointed out that "the ability of the patient to carry on his daily activity without symptoms usually tells more about his myocardial power than can be discovered on examination of the heart." Secondly, it will be some time before electrocardiographic, x-ray and other laboratory procedures are available in every case subjected to major surgery.

A patient was not considered hypertensive unless a systolic pressure of 160 or more was accompanied by a diastolic pressure of 100 or more. These levels were deliberately made higher than life-insurance norms in an attempt to exclude transient elevations due to emotional disturbances. Furthermore, if only one or two readings were above this level and the majority were lower, the patient was not classed as hypertensive.

The classification of the patient's nutritional state may not receive general acceptance. Lack of data made it impossible to classify each patient in terms of percentage above or below norms for a given age, height and sex. They were therefore listed according to the examining physician's appraisal, which was either "obese," "well-developed and well-nourished" or "poorly nourished." That this inexact classification of obese or malnourished implied a significant departure from normal may be inferred from the fact that this required a detailed note in longhand in contrast to the check marks that were used on a printed form when the patient appeared normally nourished.

The duration of the operation was likewise found to influence surgical mortality, probably because duration is likely to parallel the severity of the procedure.

In Table 2 the operative mortality for all cases is contrasted with that for the various groups. The mortality for long operations (two hours or

more) was very high (46.7 per cent), in contrast to 12.1 per cent for all operations under two hours; and those patients with a cardiac history, malnutrition or an age of sixty or over had a considerably higher mortality rate than did the total population of the study. The mortality of the

TABLE 2. Operative Mortality.

CLASSIFICATION	NO. OF CASES	MORTALITY %
Total cases	2445	15.8
Obesity	266	7.9
Malnutrition	565	25.3
Old age (over 60)	1081	23.8
Hypertension	347	16.4
Cardiac history	346	24.6
Long operation (over 2 hours)	244	46.7
Short operation (under 2 hours)	2201	12.1

obese group was below that for the total population, and the rate of the hypertensive group was practically the same as that of the total.

With the realization that combinations of these variables were common and that the true picture might easily be masked because of the interrelation between them, the variables were subjected to partial association. For example, a group of patients might all have cardiac disease and hypertension and be aged. The problem was to determine whether all three variables contributed to the high operative mortality of the group, or whether only one was responsible, the seeming relation of the other two being simply due to the combined presence of all three variables. It was recognized, moreover, that differences in mortality inherent in the type of operation must be taken into account in these calculations. The analysis of plural variables, in which the data are grouped as present or absent, requires working with partial association, which is the effort to eliminate the fallacy of mixed classification by using partial universes.

Subuniverses were constructed, and the mean of the combination of all the universes for a given variable was compared with its standard deviation. The criterion of measurement of significance was 2.6, *p* equaling 0.01. The results follow: obesity -0.8; malnutrition 1.97; old age (over sixty years) 3.5; hypertension 1.17; cardiac history 1.86; long operation (over two hours) 4.0. Only the figures for the aged and for length of operation are significant. The clinician who may have been frightened off by the statistical method of approach is referred to Table 3 in which the operative mortality is given for each pure subgroup. All patients in any given group in this table were afflicted with only one of the presumable contraindications to operation. The conclusions to be drawn from

contrasting these mortality rates with the total mortality of 15.8 per cent are substantially the same as those already reached by the method of partial association.

This clearly indicates that the only variables of importance in this selection of cases were the prolonged operation and the age of the patient. It is

TABLE 3. *Relation Between Operative Mortality and "Pure" Presumable Contraindications to Surgery.*

CO-CONTRADICTION	NO. OF CASES	MORTALITY %
Obesity alone	113	2.7
Malnutrition alone	210	14.8

Hypertension alone	80	11.2
Cardiac history alone	59	15.3
Long operation (over 2 hours) alone	62	27.4

impossible to postulate from this study whether similar results would be obtained in another series, since the choice of patients might easily vary.

Table 4 lists the immediate causes of death in their order of importance for the total 386 deaths.

TABLE 4. *Causes of Postoperative Deaths.*

CAUSE OF DEATH	TOTAL CASES (386)	AUTOPSIED CASES (216) %
Sepsis	35.8	40.3
Pneumonia	26.9	26.1
Cardiac failure	11.1	11.1
Pulmonary embolism	7.3	7.5
Hemorrhage	4.9	5.7
Renal failure	3.1	3.1
Surgical shock	4.9	4.9
All other causes	6.0	1.3

Warren¹ in a study of 252 postoperative deaths coming to autopsy found the immediate cause of death to be in order of their incidence: sepsis,

TABLE 5. *Causes of Postoperative Death Subdivided According to Criteria of Operability.*

TOTAL DEATHS	CAUSES OF DEATH					ALL OTHERS
	SEPSIS	PNEUMONIA	HEART FAILURE	PULMONARY EMBOLISM		
Obesity alone	3	—	—	1		1
Malnutrition alone	31	12	10	2		7
Old age (over 60 years) alone	93	37	26	10	8	12
Hypertension alone	9	5	—	1	1	2
Cardiac history alone	9	4	2	—	—	3
Long operation (over 2 hours) alone	17	7	6	—	—	4

pulmonary embolism, pneumonia and cardiac failure.

Table 5 shows the distribution of these causes among our patients having to their discredit only malnutrition, hypertension, cardiac history, old age, long duration of operation, or obesity. As might be expected, the same approximate relation exists for the chief causes of death: sepsis, pneumonia, heart failure and pulmonary em-

bolism. The low incidence of heart failure among the "pure" cardiac patients and "pure" hypertensive patients coincides with the observations of Butler, Feeney and Levine⁴ that, even among patients with heart disease, heart failure was seldom the cause of postoperative death. Brumm and Willius⁵ also found only 4.5 per cent cardiac deaths postoperatively among 257 patients with severe coronary disease. These observations must be contrasted with Sprague's³ report of heart failure's responsibility for 50 per cent of the postoperative deaths in a group of 170 cardiac patients.

The mortality for different types of anesthesia is listed in Table 6. One must be cautious about

TABLE 6. *Mortality with Different Types of Anesthesia.*

ANESTHESIA	NO. OF CASES	NO. OF DEATHS	MORTALITY %
General	1339	148	11.1
Local	524	102	19.5
Spinal	339	75	22.1
Mixed (more than one)	227	58	25.6
Totals	2429*	383	

*In 16 cases there was no record of the anesthesia.

drawing conclusions from these figures, since so-called "safe" anesthetics like novocain were often used in emergency or palliative operations when the patient was in a very poor condition. The strikingly higher mortality in cases in which more than one anesthetic was employed was probably due to difficulties inherent in the procedure, which increased the length of the operation so that spinal anesthesia had to be supplemented with general or with local anesthesia. The importance of the duration of the operation has already been discussed. Because a given operation usually postulated a certain type of anesthesia, it was not possible to com-

pare the hazard of different types of anesthesia in a particular operation in which the expected mortality was well established.

Since the age of the patient and the duration of the operation appear to be the most important factors in determining operative mortality, the interrelation of these factors demands examination. With an operation that lasted longer than two hours, the mortality among patients over sixty

years of age was 1.7 times as great as that among those under sixty. Among those with an operation of less than two hours' duration, the mortality rate of patients over sixty was 2.6 times as great as that of those under sixty. A comparison of the over-sixty group with over two hours' operations with the over-sixty group with less than two hours' operations shows the former to be 2.9 times as great. It appears that both variables are of great significance in operative mortality, and the long operation is probably the more important of the two.

SUMMARY AND CONCLUSIONS

In the work done at the Pondville and Westfield cancer hospitals, such variables as obesity, malnu-

trition, cardiac history and hypertension are apparently of little value in determining operative mortality; the age of the patient and the length of the operation are of considerable importance, with the latter perhaps the more significant of the two.

THE PROTHROMBIN LEVEL IN EARLY INFANCY*

Its Relation to Hemorrhage and Other Neonatal Disturbances

GEOFFREY EDSALL, M.D.†

BOSTON

WHIPPLE¹ observed over twenty-five years ago that hemorrhagic disease of the newborn might be associated with an extremely low plasma prothrombin. Brinkhous et al.² using a method³ of prothrombin titration much more precise than any previously employed, demonstrated that the majority of newborn infants had moderately low prothrombin titers. Moreover they found that one infant, suffering from hemorrhage, had only 5 per cent of the normal adult level. The present report is the result of an attempt to define further the relation between neonatal hemorrhage and plasma-prothrombin deficiency.

MATERIAL AND METHODS

Prothrombin determinations were made on bloods obtained from 27 infants at the Infants' Hospital, the Children's Hospital and the Boston Lying-in Hospital.‡ Blood drawn from the internal or external jugular vein was added to about one tenth of its volume of 3 per cent sodium citrate in a graduated tube, and centrifuged for twenty to thirty minutes at 2000 revolutions per minute; the hematocrit was noted, and the plasma drawn off. The method of prothrombin titration was modified slightly from that of Quick.⁴ Plasma in

0.5-cc. amounts was placed in clean test tubes in a water bath at 37°C. To each 0.5 cc. of plasma was added enough 0.9 per cent sodium chloride solution to give a final volume of 1 cc. after the further addition of 0.2 cc. of human placental coagulant⁵ and approximately 0.05 cc. of 2.5 per cent calcium chloride solution. The prothrombin time was taken as the interval between the addition of calcium chloride and the gelation of the contents of the tube. The optimum amount of calcium chloride to be added was determined for each plasma, since it was found, in agreement with others,^{6,7} that unless this precaution was observed distorted prothrombin times might be obtained. Human placental extract (freshly prepared each week) was employed rather than animal tissue, since it gave a longer prothrombin time, which could be measured with greater accuracy. Citrate was preferred to oxalate, since it forms no precipitate on the addition of calcium ions.

The empirical correlation between prothrombin time and plasma-prothrombin concentration was determined by testing serial dilutions of normal plasma with prothrombin-free plasma. Plasma was rendered prothrombin free by absorption with alumina⁸ or by repeated passage through a Seitz filter.⁹ The values obtained in several such test runs are presented in Table 1, in the form of the ratio of the clotting time of the sample with diminished prothrombin to that of the normal control. The values presented differ somewhat from those described in the earlier reports on the subject.^{1,10}

but correspond closely to those published by Quick¹¹ in 1938

Estimates of plasma prothrombin were reported in terms of the percentage of the adult normal, to the nearest 5 per cent, except that values from 70 to 100 per cent were entered as "70+," accurate determinations in these ranges being unreliable unless a more refined method is employed. It was found impossible to establish with certainty a critical level of plasma prothrombin, below which bleeding might be regularly expected; in various reports on this subject the "critical level" is given

infant was first seen at the Infant's Hospital when nineteen days old. Early neonatal data could not be obtained, but a tentative diagnosis of erythroblastosis was made. Dam, Tage-Hansen and Plum¹⁷ have recently published the finding of a very low plasma prothrombin titer in this condition.

as 20 per cent,¹² 13 35 per cent,¹⁴ 30 to 50 per cent¹⁵ and 50 per cent.¹⁶ In the absence of any general agreement on this point, the level of 30 per cent was tentatively selected as being most consistent with the available findings

RESULTS

Thirty-nine blood samples from 27 infants less than five weeks old were titrated; the data are presented in Table 2. All specimens were obtained from infants under special observation, and hence the data do not represent a cross section of normal infancy in this age group. Neither in infants nor mothers received vitamin K during this study. In Cases 1 to 6 the patients were apparently healthy infants. In Case 7 the child had a colon bacillus septicemia from which he recovered. Cases 8 to 19 included 12 patients manifesting signs of hemorrhage other than intracranial bleeding alone.

Eleven infants (Cases 12, 13, 15, 16 and 21 to 27) were diagnosed as having some intracranial injury (neonatal asphyxia or intracranial bleeding). The patients in Cases 18 and 20 vomited all feedings from birth for about one week. In Case 19 the

each of the above groups are summarized in Table 3

DISCUSSION

The above data indicate a wide variation in the plasma prothrombin level in early infancy, both in normal and in abnormal infants. Quick^{18, 19} has reported a high prothrombin level at birth, followed by a drop in the next forty-eight to seventy-two hours, and a subsequent rise toward the normal adult level during the ensuing week. These findings show a close correlation with the known variation in bleeding and clotting times during the neonatal period.^{20, 21*} In the cases here presented, however, such a relation was not regularly observed. Whereas in Cases 2, 15, 16 and 23 a low prothrombin in the first two or three days was succeeded in two to five days by a considerably higher level, Cases 12 and 20 exhibited a stationary or even a falling titer over a similar period. Thus, although Quick's observations probably represent the normal course of prothrombin fluctuation in young infants, this sequence of events may be disrupted by pathologic disturbances in early neonatal life. This possibility is borne out further by the prothrombin levels observed in the 11 patients showing evidence of intracranial injury. As seen in Table 3, the average prothrombin titer in this group was abnormally low. This observation may be correlated with the recent substantiation by Clifford²² of the observation that a large pro-

*7 Allen et al.²³ find neonatal prothrombin titer by the method to be much lower than those reported by various workers using Quick's method. They question the validity of the latter method for prothrombin determination on the newborn and offer evidence that the low neonatal prothrombin titer may be in effect partially offset by an increased convertibility of the prothrombin at birth. Pending further data on the validity of the various methods for prothrombin estimation, the use of Quick's method seems satisfactory particularly since it represents an actual measure of the efficiency of the prothrombin.

portion of infants with hemorrhagic disease of the newborn have a definite history of neonatal asphyxia. Clifford²⁴ has also drawn attention to the significant degree of liver damage found in infants dying with neonatal asphyxia—an observation of particular value in view of the known dependence of the blood prothrombin level on the integrity of the liver.²⁵ Hence it appears that neonatal asphyxia may in a certain number of cases be closely associated with the appearance of neonatal hypoprothrombinemia, if it is not in fact influential in the production of this condition.

No definite relation between prothrombin titer and clinical hemorrhage was observed. Whereas 8 patients with levels below 35 per cent (range 5 to 25 per cent, average 12 per cent) manifested a hemorrhagic tendency, 8 other patients with subcritical levels (range 15 to 30 per cent, average 22 per cent) showed no tendency to bleed. On the other hand, 4 of the 11 patients with initial prothrombin levels above 30 per cent exhibited melena. This melena, however, was not severe in any case, nor was it accompanied by other signs of a bleeding tendency. By contrast, 7 of the 8 bleeders with prothrombin levels of 30 per cent or less manifested either severe bleeding, a marked anemia or both, and all 7 had either a prolonged bleeding time or else bled for several hours from a skin puncture. In general, it was noted that infants with prothrombin titers below 15 per cent tended to bleed severely; those with titers from 15 to 30 per cent did not always bleed, but when they did, the hemorrhage was usually severe, whereas infants with titers above 30 per cent, though they might bleed, did not manifest more than transitory hemorrhage. Thus hemorrhagic disease of the newborn appears to be a syndrome in which two types of hemorrhagic tendency may be distinguished. There is a mild group having no intrinsic coagulation defect, in which transitory bleeding is probably induced by some factor such as gastrointestinal irritation from the primary bacterial invasion of the digestive tract,²⁶ vascular congestion or rupture of minor blood vessels during delivery. Severe bleeding, on the other hand, appears to have a close correlation with a low level of plasma prothrombin, and in the series of cases presented showed a close relation to prolonged bleeding time. The latter group might be regarded as having genuine hemorrhagic disease of the newborn, and must be differentiated from the first group in any evaluation of the etiology or therapy of this syndrome.

The very low prothrombin levels observed in Cases 18 and 20, in both of which severe nutritional disturbances were present, may be related

to the finding that the maintenance of a normal plasma-prothrombin level, even in an adult, is dependent on adequate assimilation of vitamin K.²⁷ In this connection, the recent reports of an elevation in the neonatal prothrombin level, following oral administration of vitamin K to newborn infants²⁸⁻³⁰ or to mothers before delivery,^{29, 30} are of great physiologic as well as clinical significance.

No correlation could be observed between prothrombin titer and duration of labor. Nor was any relation apparent between prothrombin level and birth weight. We were unable to confirm the correlation reported by Hellman and Shettles³⁰ between prematurity and low plasma prothrombin.

SUMMARY

Plasma prothrombin titrations were performed on thirty-nine venous bloods from 27 infants between the ages of three hours and twenty-five days. All but 6 of the infants were studied while under observation for some neonatal disturbance.

Titers ranged between 5 and 70+ per cent of the adult normal. No correlation could be observed between plasma-prothrombin level and birth weight or duration of labor.

Nine of 11 infants observed following neonatal asphyxia or intracranial hemorrhage had prothrombin titers below 35 per cent.

Although no absolute relation was observed between the prothrombin level and the tendency to hemorrhage, it was noted that infants with titers below 15 per cent tended to bleed severely; that infants with intermediate levels (15 to 30 per cent) might or might not bleed—when they did bleed, the hemorrhage was usually severe; and that infants with titers above 30 per cent sometimes manifested a transitory melena, but none in this series exhibited a severe bleeding tendency.

TABLE 2. *Clinical and Laboratory Data on Cases Studied.*

CASE No.	COMPLICATIONS OF PREGNANCY	DELIVERY	DURATION OF LABOR hr.	BIRTH WEIGHT lb. oz.	CLINICAL CONDITION	AGE OF INFANT	PROTHROMBIN LEVEL
						days	%
1	Latent syphilis	Forceps	11	7 4	Normal	$\frac{1}{8}$	70+
2	Latent syphilis, toxemia	Normal	2	6 10	Normal	3	70+
3	None	Breech	11	6 12	Brief period of resuscitation at birth	$\frac{1}{2}$	20
4	Diabetes	Normal	$3\frac{1}{2}$	5 10	Normal	4	35
5	None	Face presentation	$9\frac{1}{2}$	8 2	Pseudocyanosis, due to face presentation	1	40
6	Banti's disease	Normal	12	9 12	Normal	2	25
7	None	Normal	17	9 3	Colon-bacillus septicemia; discharged improved on 44th day	1	70+
8	None	Normal	$2\frac{1}{2}$	4 4	Three tarry stools on 2nd day; red-cell count 6,000,000, bleeding time 1 minute, clotting time $5\frac{1}{2}$ minutes	2	70+
9	None	Normal	21	9 4	Bloody vomitus at 2 hours; bloody stools at 24 hours; red-cell count 5,300,000, bleeding time 5 minutes, clotting time $3\frac{1}{4}$ minutes	25	70+
10	None	Normal	33	9 0	Coffee-grounds vomitus and tarry stool on 3rd day; red-cell count 5,200,000, bleeding time $2\frac{1}{2}$ minutes, clotting time 2 minutes	3	60
11	Hydramnios	Normal	10	8 15	Catheter resuscitation at birth, old blood in stools at 3 days; red-cell count 3,700,000, hemoglobin 87%, bleeding time 3 minutes, clotting time 4 minutes	4	50
12	Toxemia	Induced	10	6 1	Catheter resuscitation at birth, grossly bloody stools and marked dehydration at 2 days, old intracranial hemorrhage confirmed at 14 days; red-cell count 6,500,000 to 7,200,000, bleeding time 4 minutes, clotting time 5 minutes	3	25
13	None	Normal	24	5 0	Cyanotic attacks for 3 days after birth; bleeding for several hours from heel puncture; red-cell count 6,760,000, bleeding time 2 hours, clotting time not determined	7	10
14	None	Normal	?	9 0	Bloody vomitus and stools at 2 days; red-cell count 3,200,000, bleeding time 22 minutes, clotting time 6 minutes; transfusion given	24	70+
15	Funnel pelvis	Forceps	21	7 13	Given oxygen at birth; forceps hematoma of jaw, pink-stained vomitus and high-pitched cry at 36 hours; red-cell count 3,500,000, bleeding time 15 minutes, clotting time 3 minutes; on 4th day bleeding time 4 minutes, clotting time $4\frac{1}{2}$ minutes; lumbar puncture showed 540 red cells, mostly crenated	2	20
16	Prenatal vaginal bleeding	Induced	$3\frac{1}{2}$	8 13	Neonatal asphyxia, multiple ecchymoses, bleeding for 7 hours from heel puncture; red-cell count 5,000,000, bleeding time $6\frac{1}{2}$ minutes, clotting time 12 minutes; lumbar puncture suggested intracranial hemorrhage	4	15
17	Pyelitis	Normal	6	10 6	Red-tinged vomitus at 24 hours, recurring later on second day, heel puncture oozed for 24 hours, red-cell count 5,280,000, bleeding time $9\frac{1}{2}$ minutes, clotting time 13 minutes; transfusion given	7	60
18	None	Normal	?	9 11	Vomiting until 8th day, when operation relieved duodenal stenosis; heel puncture bled for 7 hours on 8th day; bleeding time not determined, clotting time 15 minutes, hemoglobin 80%	2	5
19	None	Normal	3	?	Jaundice on 3rd day, spontaneous ecchymoses from 10th day; cord stump bled intermittently after 12th day until transfusion was given on 19th day; operation at 8 weeks disclosed inspissated bile in common duct; red-cell count 1,640,000, bleeding time 30 minutes, clotting time not determined	8	5
20	None	Normal	14	7 7	Vomited all feedings from birth until regulated with thickened feedings at about 1 week; red-cell count 5,400,000 on 3rd day	19	5
21	Toxemia (mild)	Forceps	5	8 9	Mild cyanosis for 6 hours; marked caput succedaneum	3	15
22	None	Normal	7	9 11	Severe neonatal asphyxia; died in 16 hours	9	15
23	None	Breech	2	7 9	Right monoparesis at 1 day; lumbar puncture (2 days) showed 6000 red cells, all crenated	1	25
24	Hypertension in 45-year-old mother	Normal	24	7 14	Neonatal asphyxia with recurrent dyspnea on 2nd day; lumbar puncture showed 18,000 crenated red cells; diagnosis of residual high cervical-cord injury made at 3 months	$\frac{1}{2}$	30
25	Toxemia	Normal	2	8 13	Cyanosis and tense fontanelle on 3rd day; cyanosis still visible on 13th day; lumbar puncture unsatisfactory	1	20
26	None	Normal	14	9 12	Convulsive episodes from 2nd to 10th day; calcium therapy instituted on 10th day; lumbar puncture unsatisfactory, bloody tap (?)	5	70+
27	None	Breech	38	7 0	Head and shoulder injuries at birth; subdural hemorrhage; left subdural tap at 14 days showed 7200 crenated red cells	2	20

the patients had left the hospital after treatment for their injuries.

Diabetes insipidus may fall into a different category. The evidence is still too meager to justify a more definite statement, however. So far as it goes in support of trauma as a possible cause of this other type of diabetes, Bréhant, on the basis of one case, states that it cannot be regarded as rare or unusual and then "rings all the changes" on the old theoretical concepts of its cause.

SPINE AND SPINAL-CORD INJURIES

Although only remotely connected with the problem of spine and spinal-cord injuries, the papers by Zelig⁸ on congenital absence of the sacrum, by Kuhns et al.⁹—among other subjects—on motion in the vertebral column and by Batson¹⁰ on the function of the vertebral veins and their role in the spread of metastases merit detailed study. I can add another case to Zelig's collection and a note to the effect that, at the same time, there was another child in the wards who had a double sacrum; both cases were seen in consultation with Dr. Louis G. Howard. The importance of Batson's work can hardly be overestimated; any surgeon who deals with malignant tumors and their metastases should make himself familiar with it.

Papers on all aspects of rupture of the intervertebral disk, the protrusion of the nucleus pulposus and its compression of the cord, the cauda equina or the individual spinal roots continue to flood the literature. The best opinion today seems to be that a certain diagnosis of a protruded nucleus can be made only when there is a reasonably connected history of back injury, an increase of total protein content above normal in the specimen of cerebrospinal fluid that was collected closest to the assumed level of protrusion,—other samples having a normal content,—a defect, visualized by x-ray study in the intra-arachnoid column of lipiodol or air with or without a partial block, and finally a demonstration of peripheral neurologic changes that are characteristic of radiculitis and that can be explained only on the basis of an irritation or compression of one or, at most, two adjoining roots. Of all these requirements, the last is by far the most important. Indeed, my experience leads me to believe that when the tumult and the shouting have died down, it will come to be recognized as the one indispensable prerequisite for this diagnosis.

Air or, better still, oxygen is gradually replacing lipiodol as a means of visualizing the outlines of the spinal canal. Chamberlain and Young's¹¹ paper is most convincing. Poppen¹² re-

ports that "oxygen spinograms on 175 patients suspected of having herniated intervertebral disks were thought to be positive, and later verified by operation, in 150." On the other hand, Hampton¹³ reports an accuracy of 93 per cent in 133 cases in which iodized oil was used intrathecally. He strongly favors the use of this medium in preference to oxygen, even though he recognizes that the oil is a foreign body and may act as such in producing disturbing or dangerous effects. In this connection, Garland and Morrissey¹⁴ report finding intracranial collections of iodized oil some years following lumbar myelography in approximately two thirds of a series of 25 cases. However, they found no case in which any symptoms or positive neurologic findings could be ascribed to the presence of the oil. A more widespread use of oxygen or air is undoubtedly retarded by the technical imperfections of the method. These result in underfilling or overfilling of the sac and consequent poor visualizing of the edges of the column of oxygen.

It is still generally agreed that adequate orthopedic treatment should precede the use of laminectomy as a method of treatment of protruded nuclei. If laminectomy is used, the removed bone should never extend beyond one or two adjoining laminae on one side only. Mixer and Barr¹⁵ state that it is necessary to cut away only the upper and lower edges of two adjoining laminae. Hamby¹⁶ describes an interlaminar removal of the protrusion that he believes to be possible in some cases. It appears that, with such minimal bone removal and ligamentous damage, the operative removal of a protruded nucleus does not per se require subsequent fusion of the spine.

An end-result study of the bone lesions accompanying spinal-cord injuries in 76 cases is reported by Munro and Wegner.¹⁷ They point out that the therapy and prognosis of cervical-spine injuries that do not involve the spinal cord or are already chronic when first seen are quite different from those in which the cord injury plays a part and in which the patient comes for treatment immediately following the injury. Treatment in the combined cases is conditioned by the therapeutic needs of the damaged cord and the presence or absence of a spinal subarachnoid block. Fifty per cent of their patients died within the first forty-eight hours, and 45 per cent before discharge and as the direct or remote result of the injury. Abandonment of immediate laminectomy reduced their mortality 30 per cent. Twenty-eight of the 30 living patients had satisfactory end results, and 4 others died of intercurrent disease. These authors believe that the use of plaster-of-Paris casts

in cervical-cord injuries is dangerous and ordinarily contraindicated. In this connection, they¹⁸ have modified and used with satisfaction an adjustable cervical spinal brace. In connection with cervical spinal injuries and perhaps of importance from the industrial aspect is the report by Hanflig and Schlosberg¹⁹ of a rare case of nontraumatic dislocation of the atlantoaxial joint.

General care of spinal-cord injuries. Adequate tidal drainage of the urinary bladder is or should be an essential part of the general care of all spinal-cord and cauda-equina injuries. The original apparatus devised for this purpose was never intended to irrigate the bladder except as a secondary function. Its prime purpose was to permit the surgeon to adjust the intravesical pressure to the type of bladder that the apparatus was serving, and by regular emptying, in addition to a minimum of irrigation with some antiseptic solution, to counteract the deleterious effect of the residual urine that was necessarily always present. The inability to deliver significant quantities of irrigating solution to the bladder has now been overcome by one of the modifications of the apparatus devised by MacNeill and Bowler.²⁰ This improved tidal-drainage apparatus, as diagramed in Figure 6 of their article, should replace the original in the treatment of so-called "neurogenic bladders." When it is used, however, a change should be made in the irrigating fluid. If a 1:30,000 solution of potassium permanganate is introduced into a bladder in the large quantities that are permitted by this apparatus, either a mucous or alkaline cystitis is set up. In the latter event, calculi will form. These complications can be avoided by the use of 0.5 per cent acetic acid instead of the permanganate solution.

In line with the cystometrograms that are a necessary part of tidal-drainage therapy, White, Verlot and Ehrentheil²¹ have adopted the U type of cystometer²² for use in a study of activity of the colon. They have found that the colon is the physiologic analogue of the bladder. It has the same stretch reflex and the same ability to distend, to act as a reservoir and to initiate emptying contractions in response to a sensory stimulus caused by a given amount of fill. Its activity is governed by a spinal reflex, and emptying contractions may be inhibited but not initiated by impulses from the cerebral cortex.

With the overlapping of neurologic into genitourinary surgery, an authoritative statement concerning the use and abuse of the urethral catheter will be welcomed by neurosurgeons. This is found in Quinby's article.²³ The bacteriology of urinary-tract infection is well covered by Scholl et al.,²⁴ and the present status of urinary antisepsis by Cul-

ver and Seifert.²⁵ An interesting case of neurogenic dysfunction of the bladder due to spinal anesthesia is reported by Peirson and Twomey.²⁶

PERIPHERAL-NERVE INJURIES

With the advent of war, articles about peripheral nerve injuries again begin to appear in the literature. That war is not necessary to the proper understanding of perhaps the most important of all peripheral-nerve problems is evidenced by the article on the traumatic lesions of the nerves of the wrist and hand by Dr. Torr Wagner Harmer.²⁷ This classic was published shortly after his death and may well serve as a fitting memorial to him. In it the reader will find the last word on this subject.

From Germany comes an article by Ehalt.²⁸ He cites an experience with 77 cases of nerve injuries and advises that in cases of open nerve injuries immediate suture is required, but that in closed nerve injuries operation should not be performed until six months have elapsed, since the outlook for recovery is very favorable. Leriche²⁹ calls attention to the variability of results and their dependence on the particular nerve involved. He believes that traction on peripheral nerves prevents good healing. The best work comes from England. Three articles in the *Lancet* should be read in detail by all who are interested in this problem. One is by Cairns and Young³⁰ on the whole subject of treatment of gunshot wounds of the peripheral nerves; another is by Young and Medawar³¹ and concerns fibrin suture of peripheral nerves, with particular reference to the measurement of the rate of regeneration; and the third is by Young, Holmes and Sanders³² on the importance of the peripheral stump and the value of nerve grafts in nerve regeneration.

Finally, a paper by Homans³³ should be mentioned because of its importance as explaining one of the causes of hitherto unexplainable pain in the extremities. He speaks of it as "minor causalgia" and defines it as a "hyperesthetic neurovascular syndrome." It comes about in patients in whom probably "there is something basically at fault about the nervous system." Abnormal and painful neurovascular reflexes involving the sympathetic fibers in the vessels of the extremity and their connections with the central nervous system on the one hand and the small vessels on the other are initiated by apparently trivial peripheral stimuli. Fortunately these painful symptom complexes can usually be relieved by sympathetic-nerve block. Characteristic changes in the temperature, general appearance, color and often temperature of the skin in the painful area occur. The severer forms are associated with local injury and may be very chronic.

EPILEPSY

Gibbs³⁴ published in December, 1939, an extremely important paper on electroencephalography in epilepsy. In this study he presented clearly the present concept of epilepsy as exemplified by electroencephalographic and other associated diagnostic studies. From this work it is apparent that "fits" do not accompany all epileptic attacks, that there is a definite hereditary factor in the disease and that pathways of new investigation have been so opened out that one can say with the author that electroencephalography "has revolutionized the study of epilepsy." The following April, Lennox,³⁵ in a more general paper on the treatment of epilepsy and migraine, re-expressed the essentially diagnostic data published by Gibbs and added certain other facts concerning the relation between this disease and migraine and the various available methods of treatment with their advantages and drawbacks. No pediatrician, general practitioner, neurologist or neurosurgeon should fail to read these two papers in detail; no one today can either properly diagnose or properly treat epilepsy unless he is thoroughly familiar with their contents.

MISCELLANEOUS

Bedsore is a source of trouble and annoyance to nurses, patients and doctors alike. This is especially true in association with spinal-cord injuries. Munro³⁶ has presented evidence to show that in spinal-cord injuries there is reason to believe that all bedsore are preceded by pressure sores, which in turn develop because of too prolonged pressure on bony prominences, maceration of the skin, with destruction and removal of the protective horny layer, and local infection. In the presence of spinal-cord injury that destroys motor reflex activity—that is, spinal shock—and particularly in association with thoracic-cord injuries, the peripheral vasomotor reflexes cease to act. This causes spreading radial necrosis and the characteristic bedsore, as contrasted with the pressure sore. The treatment recommended is to move such patients once an hour; to prevent the development of any serious exhaustion by appropriate feeding, transfusions, administration of vitamins and the like; to prevent the occurrence of general sepsis and to maintain a constantly dry bed by the proper use of a tidal-drainage apparatus; and to avoid all forms of external artificial splinting or support to the spinal column so long as the patient with a spinal-cord injury is bedridden. This therapy is especially important in the thoracic-cord injuries. In connection with this work, it was noted that the patients had a severe hypoproteinemia, and that pressure sores and bedsore were already es-

tablished could be healed only by the feeding of very high protein diets. Ravdin,³⁷ Elman,³⁸ Holman³⁹ and Koster and Shapiro⁴⁰ all write on various aspects of this problem, although not directly about bedsore or pressure sores. Brooks and Duncan^{41, 42} contribute significant data on the effects of temperature on the survival of anemic tissue, and the effects of pressure on tissues in general.

Shuman and Jeghers⁴³ report their findings in relation to the value of routine blood-protein determinations in 320 consecutive cases.

Crandon, Lund and Dill⁴⁴ report on experimental human scurvy, and Lund⁴⁵ on the effect of surgical operations on the level of cevitamic acid in the blood plasma. Along this general line Elkinton, Gilmour and Wolff⁴⁶ contribute a useful paper on the control of water and electrolyte balance in surgical patients, and Maddock and Collier discuss the sodium chloride metabolism⁴⁷ and the water and electrolyte balance⁴⁸ in connection with surgical problems. Finally, Drew, Scudder and Papps⁴⁹ describe four simple tests by which data can be obtained in an emergency to determine the degrees of water and of water plus protein loss, to anticipate the onset of shock and differentiate it from simple circulatory collapse, to detect dehydration and to direct treatment more rationally for the alleviation of any of these conditions.

**CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITAL**ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor***CASE 27181****PRESENTATION OF CASE**

A fifty-eight-year-old Russian-American entered the hospital complaining of weakness and dizziness.

The patient had been a hospital employee for twenty-five years, and four years before admission a routine physical examination was negative except for a rudimentary left ear, left palatal and facial weakness, with inability to close the left eye, and slight right torticollis; these defects had been present for as long as the patient could remember. Three weeks before admission his friends noticed that he was forgetting things, and he complained of slight weakness and dizziness. Ten days before entry the patient came to the Emergency Ward complaining of headache, wobbliness and weakness. He appeared "washed out," and his tongue was coated, but the examination was otherwise negative, the temperature being 97°F. and the pulse 88. The patient was ordered off work for four days, but at the end of that time he was suffering from headache, dizziness, fatigue, weakness, anorexia, generalized muscle pains, nausea and vomiting. A diagnosis of grippe was made, and he entered the hospital for two days; he then remained at home in bed for two days, after which he returned stating that since discharge he had been so weak that he fell when attempting to walk and was dizzy even when lying down.

The past illnesses and family history were irrelevant.

On examination the patient was well developed and well nourished, but vague and unable to cooperate. The left external ear and auditory meatus were absent. The pupils were small, but equal, the retinal vessels tortuous, and he was unable to count fingers accurately; it was impossible to make out the visual fields. A peripheral seventh-nerve palsy was present on the left, as had been noted four years previously. All four extremities were spastic, slightly more so on the left; there was no paralysis, but a definite impairment in the performance of fine movements. The tendon reflexes were equal but exaggerated, with ankle clonus and a Babinski sign bilaterally.

The tongue was dry and coated. Examination of the heart, lungs and abdomen was negative; the blood pressure was 120 systolic, 70 diastolic; the peripheral vessels were hard and tortuous, and the legs cold and mottled.

The temperature, pulse and respirations were normal.

The urine was normal. The blood showed a red-cell count of 5,300,000 with a hemoglobin of 16.5 gm. (photoelectric-cell technic), and a white-cell count of 8500. The nonprotein nitrogen of the blood serum was 18 mg. per 100 cc., and the blood Hinton reaction was negative. The stools were normal.

On lumbar puncture the initial pressure was zero; the fluid was slightly yellow; the white-cell count was 1, and the red-cell count 520 (cells not crenated), per cubic millimeter; the protein was 174 mg. per 100 cc.; the gold-sol curve was 2544521000; and the Wassermann reaction was negative.

On the fourth hospital day the patient was less confused. There was weakness of all movements of the left arm and leg, with a more marked spasticity in these limbs. The tendon reflexes were more active on the left side. Tactile fremitus was increased over the right lung base, with many coarse rales over the area. An x-ray film of the chest, taken three days later with a portable machine, showed ill-defined consolidation in both lower-lung fields, as well as in the medial portion of the right upper-lung field. The patient gradually weakened, lapsed into coma without developing further neurologic signs, and died two weeks after admission, the temperature rising to 103°F. three days before death.

DIFFERENTIAL DIAGNOSIS

DR. JOHN H. TALBOTT: This patient was fifty-eight years of age and had presumably always carried stigmas acquired in utero or at an early age. The rudimentary left ear, the left palatal and facial weakness and the right torticollis are of historical interest but are not pertinent to the discussion of the present complaint. All the presenting symptoms, as well as those which appeared during the three-week period of observation, indicate an acute and rapidly progressive process. His first complaint, which was called to his attention by his friends, was a poor memory. He had, in addition, headache, weakness, anorexia, nausea and vomiting, and dizziness. These symptoms, together with a subnormal temperature of 97°F., suggest an acute attack of adrenal insufficiency in an advanced stage of Addison's disease. The description of the weakness is particularly suggestive

of Addison's disease. Patients with this malady may fall to the floor in a heap after one or two attempted steps. There is little else to suggest a diagnosis of an Addisonian crisis, however, and I shall not consider it further.

On examination the patient was well developed and well nourished. This is presumptive evidence against certain types of cancer, either primary or metastatic. He did not have, I should say, carcinoma of the stomach with metastases to the central nervous system. Anorexia, nausea and vomiting might accompany carcinoma of the stomach, but if this disease had been responsible for the symptoms I doubt if the patient would have been described as well developed and well nourished. The first positive finding, which undoubtedly is pertinent to the discussion, is the presence of generalized spasticity. Although all the lower extremities were spastic, the left arm and leg were more so. A Babinski sign was observed bilaterally, as well as ankle clonus. These findings point to some disturbance of the motor tracts involving the right as well as the left side of the body. I should doubt if the lesions were as high up as the motor cortex, and I am inclined to place them at the site of decussation of the pyramidal tracts or lower. There is no mention made of any sensory changes, although it might have been difficult to collect precise data in a patient who had obvious central-nervous-system disease. I thought, in passing, of pernicious anemia to explain the generalized spasticity, but the red-cell count of 5,000,000, as well as a normal white-cell count, pointed against a diagnosis of Addisonian anemia. The white-cell count is also against an acute infection, such as multiple cerebral abscesses, to explain the picture. The nonprotein nitrogen was normal, and we cannot explain the nervous changes on the basis of renal insufficiency and uremia. No mention was made of any intoxication or self-administered poison, and we are forced to dismiss this possibility without further discussion. The blood Hinton reaction was negative, as was the spinal-fluid Wassermann reaction. One thinks of cerebrovascular syphilis in such a clinical picture as this, but again we must dismiss the possibility for want of more evidence. The record tells us that the initial pressure during a lumbar puncture was zero. Was that repeated? Was any statement made in the record about this interesting point?

DR. CHARLES S. KUBIK: I do not believe that it was.

DR. TALBOTT: It is unusual to get a lumbar-puncture pressure of zero without commenting on it.

DR. KUBIK: It is.

DR. TALBOTT: I wonder whether this was a valid observation, but since it was not repeated, we must accept it at its face value or even disregard it if we choose. The spinal fluid was slightly yellow, and the cell count was 1 white cell and 520 red cells per cubic millimeter. Since the red cells were not crenated, it is possible that they were introduced at the time the tap was performed and were not present in the spinal fluid before the tap. We cannot, however, attribute a spinal-fluid protein of 174 mg. per 100 cc. to trauma. If one considers the amount of protein that accompanies a red-cell count of 520, there is still a wide gap between this value and 174 mg. The presence of slightly yellow fluid is additional evidence in favor of previous mischief in the central nervous system.

I should like to see the x-ray films at this point.

DR. GEORGE W. HOLMES: We have only one film, and that was taken with a portable machine. Apparently the patient was rather sick. The evidence is not complete. I hope it will not confuse rather than help you.

In this film the right lung field looks smaller than the left. I do not think you can rely on this finding, but I think you should consider it.

Here near the root of the right lung is a dense poorly defined shadow, which could be interpreted as a mass. The heart shadow is within normal limits. There is no evidence of fluid in the pleural spaces. There are also changes in the lower part of the right lung. One way to interpret it would be to say that this mass at the root of the lung accounted for the decrease in the size of the chest, and the changes in the lower part of the chest, and that it was causing interference with passage of air into the lung. Another way to interpret it is to say this was part of a bronchopneumonic process, and that the mass was caused by enlarged lymph nodes.

DR. TALBOTT: Are you able to exclude a large pulmonary infarct or multiple infarcts?

DR. HOLMES: I think that is unlikely. It could be an acute respiratory infection, or it could be a tumor.

DR. TALBOTT: If it is tumor, does it look more like primary bronchiogenic carcinoma, a mediastinal lymphoma or a Pancoast tumor?

DR. HOLMES: If it is tumor, it is a primary bronchiogenic tumor.

DR. TALBOTT: It is not infrequent to see patients admitted to the hospital complaining of cerebral symptoms who have perfectly negative histories of disturbance in the lungs, yet we may find a primary bronchiogenic tumor that has metastasized to the brain. I recall very vivid-

ly one patient known to most of us a decade ago who had essentially that story. His presenting complaints on admission to the hospital were cerebral and not pulmonary. There was nothing in the history to suggest a primary tumor in the lung. Following a cerebral exploration a metastatic lesion was discovered, and it remained for the pathologist to tell us that it was probably primary in the bronchus. Another point in favor of a primary bronchiogenic carcinoma in the patient under discussion is the statement regarding nourishment and development. I believe that if this patient did have a tumor with metastases it was consistent only with a bronchiogenic carcinoma.

Before I came to this conference, I was inclined to put primary bronchiogenic carcinoma as a second possibility, and believed that the patient's symptoms were probably due to a cerebral vascular accident. Multiple thromboses of the cerebral vessels could give most of the findings described. With this syndrome there may be a story of forgetfulness, weakness and dizziness, and the course may be as rapid or more rapid than that observed here. It could explain everything up to the rise in temperature three days before death. If we assume the primary cause of death was cerebral thrombosis, then we can attribute the terminal rise in temperature to an infection in the lungs, or better to a pulmonary infarct, which is usually not recognized as a terminal event. In conclusion, I propose to adhere to my preconference diagnosis of cerebral thrombosis and put down as a second possibility, primary bronchiogenic carcinoma with cerebral metastases.

DR. EDWARD F. BLAND: May I ask for information about the lumbar puncture? Does that mean block above the site of puncture?

DR. KUBIK: We occasionally find a low spinal-fluid pressure in cases with increased intracranial pressure. We see it rather rarely, and usually after a previous lumbar puncture, but here it was observed at the first puncture. In some of these cases we find a herniation of the brain through the tentorium, with flattening and obstruction or partial obstruction of the aqueduct. With such a condition any escape of spinal fluid before the manometer is connected to the needle may cause the pressure to drop rapidly.

DR. BLAND: What does jugular compression do in such a situation?

DR. KUBIK: One should not try jugular compression in a situation like that. There would probably be a little rise in the spinal pressure. It might also result in death from respiratory failure.

What do you really think about the films, Dr. Holmes?

DR. HOLMES: I do not know. It would just be a guess. There is insufficient evidence, and the examination was incomplete.

DR. KUBIK: What would you guess?

DR. HOLMES: If I had to make a guess, I should agree with Dr. Talbott.

DR. AUGUSTUS S. ROSE: If it is a brain metastasis, would Dr. Talbott make a statement as to where he thinks it was?

DR. TALBOTT: It was bilateral. If cerebral thrombosis is the correct diagnosis, then there might have been several areas of softening in the brain stem. Certainly the lesions must have been below the motor cortex.

DR. ROSE: There is no definite statement about papilledema.

DR. TALBOTT: I did assume, however, that there was no increased intracranial pressure. No mention was made of retinal exudates, and there was no good description of the retinal vessels. One sentence included in the abstract is difficult to interpret: it is mentioned that it was impossible to make out the visual fields. Does this mean that the patient could not co-operate, or that the visual fields were so restricted that they could not be determined accurately?

DR. KUBIK: I should think the former.

DR. TALBOTT: That is what I assumed.

DR. KUBIK: Sometimes the examiners are too easily discouraged.

CLINICAL DIAGNOSIS

Cerebral accident.

DR. TALBOTT'S DIAGNOSIS

Cerebral thrombosis, with pulmonary infarcts,
Or primary bronchiogenic carcinoma, with metastases to the brain.

ANATOMICAL DIAGNOSES

Bronchiogenic carcinoma of the lung, with metastases to the brain.
Agenesis of the left middle ear and congenital deformity of the left auricle.
Pleuritis, fibrous.
Anthraxis, marked.

PATHOLOGICAL DISCUSSION

DR. KUBIK: This was a bronchiogenic carcinoma of the left upper-lobe bronchus, measuring about 7 cm. long and 4 cm. in diameter. Metastases were present only in the brain, and those, as usually happens, were multiple. The largest

one, measuring between 4 and 5 cm. in diameter, was in the right occipital lobe. There were smaller ones near the upper part of the motor cortex on the right, in the right temporal lobe and in the cerebellum, very near the dentate nucleus, which may, I suppose, have accounted for some of the dizziness. There was some herniation of the hippocampal gyrus through the tentorium. This probably accounted for the low spinal-fluid pressure.

The shadow seen in the x-ray film, on the right side, represents enlarged lymph nodes, in which, however, there were no metastases. The tumor itself is not visible in the film.

DR. HOLMES: I have been told by a member of your department that metastases below the tentorium are very uncommon. Do you agree with that?

DR. KUBIK: No; they are found above and below, often in the same case.

DR. HOLMES: So many of these people with bronchiogenic carcinoma die of respiratory failure that I was wondering if the metastasis to the base of the brain was the original cause of that.

DR. KUBIK: I can recall several cases with cerebellar metastases, or cases in which there were both cerebral and cerebellar lesions, those in the cerebellum being much larger and chiefly responsible for the patient's symptoms. I should agree so far as to say that metastases to the forebrain are commoner.

CASE 27182

PRESENTATION OF CASE

A forty-five-year-old French-Canadian housewife entered the hospital complaining of nausea and epigastric pain.

Twenty-five years before admission, the patient began to suffer from attacks of nausea and vomiting that lasted several days and recurred every few months. These attacks were relieved by the induced vomiting of a sour, yellow fluid. Between times her appetite was good, but she disliked fried food and sweets and believed that they initiated the attacks. Nine years before entry, recurrent attacks of moderately severe, sharp, nonradiating, high epigastric pain appeared, occurring after meals and lasting but a few minutes. Four years before admission, the patient suffered a very severe knifelike, mid-epigastric pain, which radiated to the back and was associated with nausea and vomiting. This attack lasted four days and then subsided, but recurred two years later, when it lasted one day. At another hospital, three months before admission, a laparotomy was per-

formed for an intended cholecystectomy, but a small fairly well-circumscribed mass was found on the anterior wall of the stomach near the pylorus, and another mass was noted on the dome of the right lobe of the liver. The gall bladder was said to have been filled with stones, but a cholecystectomy was not done. Because the patient had not been prepared for gastric resection, only a biopsy of the gastric tumor was performed; the specimen was reported as a slowly growing adenocarcinoma. One month before admission the patient noticed that for two days her stools were yellow; at that time she entered still another hospital, where she remained until admission here. X-ray examinations at the above institution were essentially normal, and no gastric abnormality could be demonstrated, except for pylorospasm.

At no time during this illness had jaundice been noticed, although it had been present on one occasion when the patient was ten years old; no change in the color of the urine had ever been noticed. The patient had always been mildly constipated and frequently used laxatives. She had lost 20 pounds in the year prior to operation, but had gained 7 pounds since operation.

The patient's father had died of cancer, and "numerous" aunts and uncles on her father's side had succumbed to this disease.

The patient was well developed and moderately obese. Examination was essentially negative except for a healed right-rectus epigastric surgical incision; the blood pressure was 130 systolic, 70 diastolic.

The temperature, pulse and respirations were normal.

The urine was normal. The blood showed a red-cell count of 3,400,000 with a hemoglobin of 75 per cent, and a white-cell count of 6800. The nonprotein nitrogen of the blood serum was 17 mg., the protein 6.6 gm. per 100 cc. and the chlorides 101.8 milliequiv. per liter. A blood Hinton reaction was negative; the serum van den Bergh was normal. A gastric analysis showed no free hydrochloric acid, even after histamine.

A gastrointestinal series on two occasions failed to show evidence of tumor or ulceration in the stomach. The prepyloric area was slightly elevated, possibly owing to postoperative adhesions.

A Graham test showed a faint shadow of the filled gall bladder, superimposed by the hepatic flexure. There were areas of decreased density in the region of the gall bladder, which were either stones or superimposed intestinal gas, more likely the former. The patient was unable to retain the fatty meal.

At gastroscopy a normal peristaltic wave was seen repeatedly, passing over the antrum to a tight closure, presumably the pylorus. No abnormality was visible in the antrum or pylorus. Throughout the body of the stomach there was slightly increased reddening, especially on the crests of the rugae. There was no visible verrucous appearance, ulceration or neoplasm.

A laparotomy was performed one week after admission.

DIFFERENTIAL DIAGNOSIS

DR. MYLES P. BAKER: Perhaps we might look at the x-ray films first.

DR. JAMES R. LINGLEY: Dr. Richard Schatzki performed the two gastrointestinal examinations, and since he had been warned that carcinoma of the stomach had been found at a previous operation you may be sure that he made the examination with great care. He was, however, unable to detect anything wrong with the stomach. As stated in the record, the antrum appears to be slightly displaced upward, and there is a suggestion of pressure defect here, all of which can be attributed to the previous operation. The Graham test showed a poorly functioning gall bladder, a very pale shadow with areas of rarefaction, which were quite sharply defined, round and quite consistent with gallstones.

DR. BAKER: Have you any comment, Dr. Benedict?

DR. EDWARD B. BENEDICT: I had a good look at this patient's stomach. She co-operated well. I could see the antrum and the body all the way around the stomach and could watch the peristaltic waves to the pylorus, but I could see no intragastric lesion.

DR. BAKER: I am assuming that two facts are true. One is that the biopsy diagnosis of adenocarcinoma was correct. I am also assuming that, if the surgeon were able to take a biopsy specimen from a mass described as being on the anterior wall of the stomach near the pylorus, the mass would be in the nature of a fairly large peritoneal implant. Certainly it was quite a superficial mass. We have no evidence here that the carcinoma projected from the gastric mucosa, for there was no evidence by x-ray or gastroscopy of a demonstrable mass. I should have expected that one of these procedures would have revealed a tumor, were its origin in the gland-bearing tissue of the gastric lining. It is unusual for a peritoneal implant to invade the stomach wall and cause ulceration and hemorrhage, but of course it sometimes does.

I think the description of the location of the

mass and the subsequent negative findings are more in keeping with the possibility of a secondary adenocarcinoma originating elsewhere. We have no evidence that it was primary in the colon. Presumably a barium enema was given on the second hospital admission. We have no evidence of pelvic neoplasm. The question comes up whether in the presence of known gallstones this patient could have had an adenocarcinoma primary in the gall bladder. It is true that three out of four cases of primary carcinoma of the gall bladder develop in gall bladders that contain stones, as this woman's did. Jaundice and a palpable tumor, which are commonly found with carcinoma of the gall bladder, are not present in more than 50 per cent of the cases. One could have a small carcinoma of the gall bladder and have symptoms only from metastatic disease, or of course from the associated gallstones. On the other hand, metastases from gall-bladder carcinomas are generally characterized by direct extension to the liver, and the regional lymph nodes are involved early. I think such lymph nodes would have been palpable at the previous operation, three months prior to entry here. Peritoneal metastases from gall-bladder carcinomas develop later.

What then of the possibility of adenocarcinoma originating in the body of the pancreas, which is said to develop in cases of chronic pancreatitis and may be associated with gallstones of some duration? Weight loss, which was rather prominent in this case without any story of persistent indigestion, and repeated attacks of pain sufficient to cause lack of appetite and weight loss are prominent features in the progress of cases of carcinoma of the pancreas. Abdominal pain such as this patient must have had to induce decision for surgery for gallstones can occur with carcinoma of the body of the pancreas. If that diagnosis is correct, some of the pain might have been due to the pancreatic lesion rather than to the gallstones. Metastases from such a growth are characteristically spread directly along the peritoneal surfaces from the body of the pancreas. Any tumor in the body of the pancreas could not be very distant from the peritoneal surface, and I think there is a real possibility that this tumor originated in the pancreas with metastasis to the liver and to the anterior wall of the stomach. The description, "a slowly growing adenocarcinoma," is in keeping with such a tumor. The achlorhydria is not inconsistent with such a diagnosis. About one out of six or eight cases of carcinoma of the body of the pancreas without jaundice shows achlorhydria and an anemia of varying character. I can draw no conclusions from the yellow stools mentioned here.

I am more interested in knowing whether the patient had occult blood in the stools. We have no mention of that, so that we are not sure why this patient was anemic.

DR. TRACY B. MALLORY: I am sure occult blood was searched for and not found in the other hospital. In our laboratory one stool was guaiac negative.

DR. BAKER: That does not change my diagnostic impression. I know it is possible that x-ray examination may miss a gastric tumor, but I should not expect it to miss an adenocarcinoma. Pressure defects in the region of the pylorus are not uncommonly found when the tumor is primary in the body of the pancreas.

DR. MALLORY: Dr. Sweet, will you tell us what you found at operation?

DR. RICHARD H. SWEET: We were not confronted with the necessity of committing ourselves definitely, as Dr. Baker has been this morning, so that we performed the operation with the idea of finding out what was the matter with the patient. We were impressed with the history that the previous surgeon had found a tumor of the liver, and assumed that it might be a metastatic growth. The first thing I did on entering the abdomen was to expose and take a biopsy specimen from this liver tumor, which was nodular and rather firm. It was located in the dome of the right lobe and had the characteristic appearance of a hemangioma. The Pathology Laboratory confirmed the diagnosis. The patient had gallstones, which were easily felt. The tumor in the region of the antrum was an interesting one. It measured 3 cm. in diameter. It did not feel like carcinoma; its consistence was not uniform, parts of it being firm, and other portions soft. It was attached to the first portion of the duodenum, as well as to the antrum of the stomach, and it felt to me, as I was resecting it, more like a leiomyoma or neurofibroma of the wall of the stomach. It was covered by adhesions, which had resulted from the previous exploration. It was attached to the anterior wall of the stomach, but seemed to come off from the inferior margin of the duodenum and antrum and lay in a hollowed-out depression in the head of the pancreas. Having had the biopsy report from the other hospital of "a slowly growing adenocarcinoma," we assumed that it would be best not to biopsy the tumor again, and I merely did a resection, thinking that by cutting into it I should be spreading about a malignant tumor, although, as I have said, it was a peculiar feeling tumor. I wished after I finished the operation that we had called for the slides from the hospital where the patient had been operated on before.

Having done a radical resection, we had only a few moments left to turn our attention to the cause of the symptoms, namely, the gallstones. The patient had had characteristic gallstone attacks. I therefore opened the gall bladder, scooped out the stones, which were rather large, and closed the gall bladder and then the abdomen. She has since gone home in a state of good health.

CLINICAL DIAGNOSES

Cholelithiasis.

Gastric tumor.

DR. BAKER'S DIAGNOSES

Cholelithiasis.

Carcinoma of pancreas, with metastases to liver and peritoneum.

ANATOMICAL DIAGNOSES

Cholelithiasis.

Ectopic pancreas.

Hemangioma of liver.

PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Baker and the clinicians in the hospital here made the natural assumption that, when a biopsy had been done and carcinoma reported and when that appeared to be substantiated by the presence of a metastatic nodule in the liver, there could be no doubt that the patient had cancer somewhere. That, however, was not true. As you have already heard from Dr. Sweet, the nodule in the liver was a hemangioma, an extremely common tumor in the liver, present in more than 2 per cent of all autopsies. The nodule in the stomach and duodenal wall showed on cut surface finely lobulated tissue, which was quite obviously pancreatic even on gross examination. A frozen section readily confirmed that. Nodules of ectopic pancreatic tissue are very common in the duodenum and by no means rare in the stomach. If they happen to be in or close to the pylorus, which is the common location, they may cause a little obstruction. More often, however, they are present without causing any symptoms, which I think was the case here.

The original microscopic slides from the other hospital were finally obtained and reviewed, and it was perfectly obvious in retrospect that they showed pancreatic tissue, not carcinoma. These cases are not extremely common, and I think a good many pathologists, particularly those in small hospitals, may never have seen a case. It is a natural mistake to make, although I think in any of the large hospitals the true character of the tissue would have been recognized even from a small biopsy specimen.

SUBSCRIPTION TERMS: \$5.00 per year in advance, postage paid for the United States; Canada \$7.04 per year; Boston funds \$8.52 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Saturday.

This journal does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the New England Journal of Medicine, 8 Fenway Box on Massachusetts.

Dr. A. Warren Stearns on Thursday following the annual meeting of the Society. A group of papers on vitamin therapy and one on intestinal obstruction should prove to be particularly valuable, and the talks by Dr. Frank H. Lahey, president elect of the American Medical Association, and by Dr. Philip D. Wilson, of New York City, should be very enlightening. As in previous years, there will be a continuous motion picture program, many of the films are in color, and a few are accompanied by sound effects.

The ladies' program will open with music and tea at the Gardner Museum on Wednesday afternoon, followed by the annual dinner at the Ritz Roof, where entertainment will be provided by an exceptionally good floor show. On Thursday, there will be a trip to the South Shore. Following visits to the Dorothy Quincy House and the Adams Mansion in Quincy and to the Old Ship Church and the Cushing Homestead in Hingham, luncheon will be served at Hugo's in Scituate. The trip back to Boston will be made along the famous Jerusalem Road.

The Committee of Arrangements and the Ladies' Committee are to be congratulated for devising well balanced, comprehensive and interesting programs. The attendance at the one hundred and sixtieth anniversary of the Massachusetts Medical Society should be record breaking.

ANNUAL MEETING

The program arranged for the annual meeting on Wednesday and Thursday, May 21 and 22, at The Copley Plaza, Boston, and reprinted in this issue of the *Journal*, should interest every member of the Massachusetts Medical Society.

Briefly, the two day program is divided into the following papers of general interest on the mornings and afternoons of both days — those on Thursday morning constitute a symposium on hormones, and those on Thursday afternoon, one on war medicine, seven sectional luncheon round table discussions on Wednesday, for which reservations should be made immediately, and the two annual lectures — the Shattuck Lecture, delivered by Dr. Alton Ochsner, of New Orleans, on Wednesday evening and the Annual Discourse, delivered by

SALE OF ALCOHOL IN MASSACHUSETTS

THERE is a law in Massachusetts that permits the unrestricted sale of 190-proof grain alcohol over the counter by druggists "for mechanical, chemical and medicinal purposes only," without a physician's prescription. From the nature of the statute it is evident that a buyer may use this alcohol for a beverage if he so wishes. The inadequacy of this law has sounded severe repercussions in Massachusetts. In Boston the death rate from alcoholism has increased considerably since the repeal of prohibition. In New York, where grain alcohol is available only on a physician's prescription, the death rate from alcoholism has decreased sharply since the repeal of prohibition.

Massachusetts is the only state in the Union where the unrestricted sale of grain alcohol is permitted.

The grain-alcohol problem asserts itself in the following manner. Although a person dilutes the alcohol with cheap wines and other beverages at the beginning of the alcoholic episode, the subsequent dilutions are apt to grow progressively weaker, and the blood-alcohol level may rise to a point incompatible with life.

The serious problem of alcoholism in Massachusetts has long been recognized. For example, Massachusetts ranks third among the states in incidence of mortality from alcoholism, according to Schmid.¹ Alexander, Moore and Leary² report that 4505 deaths certified by medical examiners in Massachusetts from 1928 to 1938 were directly related to the ingestion of ethyl alcohol; they also found that more deaths from alcoholism occurred in Massachusetts than from all other toxic substances combined. Dayton³ has recently revealed that, of 56,579 first admissions to Massachusetts mental hospitals between 1917 and 1939, 32 per cent of male patients were classified as intemperate and that alcoholic psychoses ranked third among the causes of admission to those institutions in 1938. Kolb,⁴ with the aid of the police departments and departments of health of several large eastern cities, showed that in 1939 the number of arrests for intoxication and of the deaths due to alcoholism per 100,000 population, respectively, were as follows: Boston, 5171 and 16.4; Baltimore, 331 and 1.9; New York, 112 and 4.5; Philadelphia, 1608 and 2.4; and Washington, 2987 and 3.9.

On March 20, 1941, a bill was heard before the Committee on Legal Affairs of the Massachusetts legislature that would greatly alleviate the problem of alcoholism by requiring a physician's prescription for the sale of grain alcohol. It received its only opposition at the hands of a paid druggists' lobbyist. It is essential that this bill should be reported favorably by the Committee on Legal Affairs. If it is to succeed, it must be wholeheartedly supported by the Massachusetts Medical Society, and each member is urged to write to his senator and representative.

OBITUARY*

LLOYD VERNON BRIGGS

1863-1941

Lloyd Vernon Briggs died at Tucson, Arizona, on February 28, 1941, in his seventy-eighth year. Such is the record of a simple fact. Not so simple is the task of portraying the personality of this man, a personality that impinged on the professional and public life of the State of Massachusetts, and ultimately made him the motivating and directing force behind a social organism that grew to proportions attracting the rest of the country, and, in fact, the rest of the world, for advice and consultation.

Dr. Briggs was born in Boston, but his roots went back into the old Plymouth Colony. Going back to many of the families that settled in and about Scituate and particularly at Hanover, his ancestry is a fair catalogue of the vigorous persons who, by growing strong themselves in that territory, helped to make Massachusetts strong. With all his other interests, very much in the foreground were affairs having to do with Hanover and its history. Among his earliest publications were historical treatises, of which the record of shipbuilding on the North River is pre-eminent. His interest was not archaeological, genealogical or even historical—it pervaded all these fields. Never an ancestor worshipper, he had felt himself to be a part of that great living organism that started so humbly three hundred years ago and developed into a substantial fraction of the nation.

No one could think of Dr. Briggs without envisioning old houses and old furniture. His eye caught the unique as well as the beautiful, and long before such collecting had become fashionable, he and his wife had garnered many precious things, not only from their own families, but here, there and everywhere. This interest and evidence of good taste reached its superlative in the house at 64 Beacon Street, though the houses at Hancock, New Hampshire, and Hanover, Massachusetts, were close rivals. So much fine furniture and so many fine furnishings seem never to have been associated with one family.

*The following statement was adopted and placed on the records of the New England Society of Psychiatry and Neurology, at its meeting at Newtown, Connecticut, April 10, 1941.

When yet a boy, Dr Briggs made a trip in a schooner to what were then the Sandwich Islands, and took part in vaccinating the native population. Incidentally, he made friendships that lasted throughout his life. From this time on he seems to have been a doctor, taking courses here and there, and especially at Tufts, Dartmouth and Harvard, but continually occupying himself with medical matters. For a few years he was concerned with the care of patients in various private sanatoriums in Massachusetts. He soon assumed responsibility for patients himself, traveling about with them or caring for them at Hancock or Hanover. In 1899 he took his medical degree from the Medical College of Virginia at Richmond. He then started active practice in psychiatry in Boston. For a while his private patients absorbed his attention, but soon the public care of the insane became the ruling passion of his life.

He soon interested himself in the Massachusetts institutions. These institutions were unquestionably good at that time, and yet there were new things to be done. A liberalizing movement was on foot, pervading all human affairs. Certain old abuses had to be abolished, and certain new techniques had to be installed. Massachusetts institutions had grown up and flourished under a system of trusteeships. These called on the best in the community for gratuitous service, and the record of one hundred years or more is undeniably good. But the germ of centralized public control had arrived, and the gradual assumption of responsibility by a state board could no longer be resisted. Beautiful as the old and perhaps more benevolent attitudes were, efficiency and standardized effort were in the air. Dr Briggs put his heart and soul into this, allying himself with many of the leading figures in America who were doing similar work in other states. One need not dwell on the bitterness aroused. It is enough to evince in the achievement of the construction of the present Massachusetts Department of Mental Health, with a single directing head. Dr Briggs did this almost alone, and it is only fair to say that almost alone he selected the late George M. Kline as the new leader of this good work in Massachusetts. This is not the place to relate the growth and development of the new department, magnificent as its proportions are, but it is the place to say that Dr Briggs followed every detail of this work with an earnestness and a vigor that were no small part of its success. He continually suggested new ideas and, not content with merely making the suggestions, saw to it that they were put into effect.

The house at 64 Beacon Street became the cen-

ter or focal point from which emanated much of the drive behind forward looking movements for the better care of the mentally sick. The whole scene was broadened, so that psychiatry, at last let out of the institutions, became a living force permeating the schools and prisons, as well as the hospitals. With it all a gentleness and kindness beamed forth so continually that all in trouble—however bad they may have been, however low their origin, however unattractive their cause—had a kind considerate hearing, and were given wholesome advice at 64 Beacon Street. Here persons with a great idea to propose found a ready enthusiasm to support them, here people crushed by adversity also went, and found a tender helping hand ready to direct them to a source of comfort or help.

In the midst of this herculean task of organizing the care of the mentally sick in Massachusetts came World War I. Dr Briggs was immediately found in uniform. While others were wondering what was the best thing for them to do, he was at Camp Devens putting mental hygiene into the Army. Soon, surrounded by a group of fellow officers, he demonstrated that even the conservatism of the military could not dampen his ardor and determination that the mentally sick should not be taken into the Army, and that if they got there, they should have the best care. Soon the great days in France came about. He seemed to be everywhere. At any rate, he knew everyone of consequence in the AEF and was one of the important figures in the Medical Department of the Army. He became an intimate friend of General Ireland and through this friendship was able to exert considerable influence in matters pertaining to military medicine. He rejoiced in the title of "Colonel" and often used it on his stationery. He often said humorously that the War Department was determined to retire him at the age of ninety.

When the war was over, there was still plenty to do. From early morning until late at night, there was incessant activity. The Division of Mental Hygiene in the Department of Mental Health was to be organized and supported. But the crowning achievement was the passage of the Briggs Law in 1923. For a hundred years there had been provisions for the examination of prisoners accused or suspected of crime, but the initiative rested entirely with partisan lawyers or indifferent officials. Out of the void came the Briggs Law, a provision ensuring the examination of persons accused of major crimes by a nonpartisan board selected by the Department of Mental Health with only nominal remuneration. This law, copied

elsewhere and praised by all, needed support for a while. This support Dr. Briggs valiantly gave. He continually tested it out and sought revision until at last it stands a model for all and a permanent monument to Dr. Briggs.

The need for classifying the inmates of the prisons had long been felt, and yet efforts to bring this about proved quite ineffective until in one interview with Governor Joseph B. Ely, Dr. Briggs succeeded in having a division set up and a budget provided for the examination and classification of inmates in prisons.

Then came the mellow days—still much to do about military affairs, still much concern about the workings of the state hospital system, but interspersed with trips to Europe, visits to the South in the winter, and longer seasons at Hancock in the summer. No one ever sat at table with Dr. Briggs as host, with every morsel of food selected and prepared under his direction, and bounteously served, without coming under the spell of his friendliness and his influence. People came from everywhere seeking advice or information—all sorts of people of all grades of society wended their ways to his fireside, and they were cordially received and directed to the best source of further information. He had a peculiarly canny side to his mind that instinctively separated and discarded the irrelevant and fastened on that part of information which was pertinent. Although his whole life was spent with mental disease, one never heard him speak of hallucinations or delusions, complexes or frustrations. He dealt with people in trouble and knew in round numbers how to help them. Although his life was spent with leaders in every walk, he always championed the cause of the underdog.

There were signs for some time that things were not right with his vascular system. This received due attention, but had no effect whatever on his emotional life. It is fitting and characteristic that in the edition of the Tucson newspaper giving an account of Dr. Briggs's death, under the heading, "Voice of the People," was a stirring letter from him to the Governor of Arizona, ending as follows:

I have never met Dr. —, but I have heard a great deal about his skill and intelligence in the care of the mentally ill, and of his knowledge of the requisites

for their care and treatment. In forcing Dr. — to resign because of insufficient appropriations, Arizona cannot but lose the respect of her sister states. This decision to tie the hands of a scientist and an expert should cause those responsible to hang their heads in shame. They have squarely turned their backs on the unfortunate sick of your state.

MEDICAL EPONYM

BRAXTON HICKS MANEUVER

The maneuver for which John Braxton Hicks (1823–1897), assistant physician-accoucheur at Guy's Hospital, London, is remembered is that described below. The quotation is from a paper "On a New Method of Version in Abnormal Labour," which appeared in the *Lancet* (2: 28–30 and 55, 1860).

Introduce the left hand, with the usual precaution into the vagina, so far as to fairly touch the feet; head, even should it recede an inch. . . . Having passed one or two fingers (if only one, let it be the middle finger) within the cervix, and resting them on the head, place the *right* hand on the *left* side of the breech at the fundus uteri. . . . Employ gentle pressure and slight impulsive movements on the fundus towards the right side, and simultaneously on the head towards the left iliac fossa. In a very short time it will be found that the head is rising and at the same time the breech is descending. The shoulder is now felt by the hand in place of the head. . . . it in like manner is pushed to the left, and at the same time the breech is depressed to the right iliac fossa. The foetus is now transverse; the knee will be opposite the os, and, the membranes being ruptured, it can be seized . . . and brought into the vagina. . . .

I . . . shall for the present confine myself to the advantages this method gives us in *placenta praevia*—at least, in every form of partial insertion. . . .

. . . as soon as the finger can enter the os, it is practicable to bring down the knee or the foot, and by that means have the command of the haemorrhage and labour at the same time; for the conical form of this natural plug is just suited to the requirements of the case. By gentle traction on the limb, the os is completely and circularly filled up; and as it dilates the size of the plug, as it descends, increases, whereby a continuous pressure can be kept up, its force varying at will according to the requirements of the case. Having then secured this plug, by keeping hold of the limb, we can afford to wait till, on the one hand, the system has rallied to bear the completion of the labour; or till, on the other, the os has dilated to permit the evacuation of the foetus.

R. W. B.

MASSACHUSETTS MEDICAL SOCIETY

THE ONE HUNDRED AND SIXTIETH ANNIVERSARY

Wednesday and Thursday, May 21 and 22, The Copley-Plaza, Boston

The exercises of the one hundred and sixtieth annual meeting of the Society will be held at The Copley Plaza, Boston, on Wednesday and Thursday, May 21 and 22. Members of the medical profession are cordially invited to attend.

The Committee of Arrangements in charge of this year's meeting consists of Drs Edward J O'Brien, chairman, William T O'Halloran, James A Halsted, George P Sturgis and Henry H Faxon.

With the exception of some of the section round table meetings and luncheons, all the meetings will be held in The Copley Plaza. The technical exhibits will fill the ball room and part of the foyer, whereas the scientific exhibits will take the balance of the foyer, the balcony boxes and the east corridor of the main floor. There will be a continuous exhibit of medical motion pictures in the State Dining Room.

The members' registration desk will be in the lobby, and it is hoped that everyone who attends will register.

The annual dinner and the Shattuck Lecture will be held on the same evening, Wednesday, May 21.

The golf tournament will be held at the Commonwealth Country Club on Wednesday, May 21.

Section round table meetings and luncheons will be held on Wednesday, May 21. As it is necessary to have, beforehand, some idea of the number who will attend these luncheons, all members are urged to notify the committee at once if they plan to come.

WEDNESDAY, MAY 21

General Clinical Meeting

9 15 to 12 00

SHERATON ROOM

Chairman Dr Bennett F Avery

9 15 *The Normal Needs and the Indications for Vitamin Therapy During Pregnancy* Dr Duncan E. Reid, Boston

9 30 *Vitamins in War* Robert S Harris, Ph D, Cambridge (by invitation)

9 45 *The Clinical Value of Vitamins* Dr William H Sebrell, Jr, Washington, D C

10 15 *Enlargement of the Heart* Dr Paul D White, Boston

INTERMISSION

10 45 *Lupus Erythematosus* Dr Richard S Weiss, St. Louis, Missouri

11 15 *Alcoholism a Problem on a Medical Service* Dr John A Foley, Boston

11 30 *Recent Advances in Chemotherapy of Infectious Diseases* Dr Chester S Keefer, Boston

11 45 *Some Uses and Abuses of Chemotherapy in Pneumonia* Dr Maxwell Finland, Boston

Supervising Censors' Meeting (PARLOR A) 10 00

Council Meeting (SWISS ROOM) 10 30

Nominating Committee (PARLOR A)

Cotting Luncheon (SWISS ROOM)
(following Council Meeting)

Section Round-Table Meetings and Luncheons

12 00 to 2 00

All round table luncheons will be \$1 00. Reservations should be made at once.

Section of Medicine

UNIVERSITY CLUB

Chairman Dr Albert A Hornor, Boston

Secretary Dr Charles L Short, Boston

Subject *The Use and Abuse of Drugs in Heart Disease*
Dr Paul D White, Boston

Section of Obstetrics and Gynecology

UNIVERSITY CLUB

Chairman Dr M Fletcher Eades, Newtonville and Boston

Secretary Dr Raymond S Titus, Boston

Subject *The Management of Bleeding in the Last Three Months of Pregnancy* Dr Frederick C Irving, presiding chairman

Section of Surgery

STATE SALON, THE COPLEY PLAZA

Chairman Dr R Nelson Hatt, Springfield

Secretary Dr Stanley J G Nowak, Boston

Subject *Fluid Administration in Surgery in the Light of Recent Advances in Water and Electrolytic Balance*
Dr John Scudder, New York City. Discussion by Dr Carl W Walter, Boston. Speaking begins at 12 45 p m.

Section of Pediatrics

HOTEL LENOX

Chairman Dr Harold L Higgins, Boston

Secretary Dr James M Baty, Belmont and Brookline

Subject *Symposium The conditioned reflex of Pavlov*
1 *Physiologic Status*

2. Practical Clinical Application, Especially to Children.

a. Gastrointestinal, urinary, respiratory and circulatory tracts.

b. Conditioned behavior.

Drs. Roy G. Hoskins, George E. Gardner and Harold L. Higgins, Boston.

Section of Dermatology and Syphilology

HOTEL LENOX

Chairman: Dr. William P. Boardman, Boston.

Secretary: Dr. Jacob H. Swartz, Boston.

Subject: *Treatment of Common Skin Diseases.* Dr. Richard S. Weiss, St. Louis, Missouri.

Section of Radiology and Physiotherapy

HOTEL LENOX

Chairman: Dr. Claude L. Payzant, Boston.

Secretary: Dr. Joseph H. Marks, Boston.

Subject: *Problems in the Management of Peripheral Vascular Disease.* Dr. Irving S. Wright, New York City.

Massachusetts Members of The New England Society of Anesthesiology

THE COPLEY-PLAZA

Presiding chairman: Dr. George C. Moore, Boston.

Subject: *Discussion of Anesthesia.*

General Clinical Meeting

2:00 to 5:00

SHERATON ROOM

Chairman: Dr. C. Sidney Burwell

2:00 *The Value of the Roentgen Examination in the Diagnosis of Intestinal Obstruction.* Dr. Eugene P. Pendergrass, Philadelphia.

2:20 *Indications for the Use of the Miller-Abbott Tube.* Dr. William O. Abbott, Philadelphia.

2:50 *Acute Intestinal Obstruction.* Dr. Leland S. McKittrick, Boston.

INTERMISSION

3:30 *Medical Organization.* Dr. Frank H. Lahey, Boston.

4:00 *Conservative Treatment of Occlusive Arterial Disease.* Dr. Irving S. Wright, New York City.

4:30 *Clinical Classification and Diagnosis of Hemorrhagic Diatheses.* Dr. William C. Moloney, Boston.

Annual Dinner (SHERATON ROOM)

7:00

The Shattuck Lecture (SWISS ROOM)

8:45

Thrombosis and Thrombophlebitis. Dr. Alton Ochsner, professor and director, Department of Surgery, Tulane University, New Orleans.

THURSDAY, MAY 22

Symposium on Hormones

9:00 to 10:45

SHERATON ROOM

Chairman: Dr. Charles E. Mongan

9:00 *Complications of Thyroid Substitution Therapy.* Dr. William T. Salter, Boston.

9:15 *The Treatment of Diabetics With Onset in 1941.* Dr. Elliott P. Joslin, Boston.

9:30 *Problems in the Recognition and Treatment of Testicular Insufficiency.* Dr. Allan T. Kenyon, Chicago.

10:00 *The Use of Female Sex Hormones in Disorders of Women.* Dr. George van S. Smith, Brookline.

10:15 *The Current Status of the Female Sex-Hormone Problem.* Dr. Roy G. Hoskins, Boston.

10:30 *The Place of Irradiation in Cancer of the Breast.* Dr. Frederick W. O'Brien, Boston, and Dr. Eugene J. McDonald, Boston (by invitation)

INTERMISSION

Annual Meeting (SHERATON ROOM) 11:00

Annual Discourse (following meeting): *The Role of the Physician in a Competitive Society.* Dr. A. Warren Stearns, Boston.

Annual Luncheon (SWISS ROOM) (following discourse)

Military Symposium

2:00 to 5:00

SHERATON ROOM

Chairman: Dr. Dwight O'Hara, Boston

2:00 *Anesthesia in War Circumstances.* Dr. Wesley Bourne, Montreal.

2:30 *Treatment of Compound Fractures Resulting from Enemy Projectiles.* Dr. Philip D. Wilson, New York City.

3:00 *The Problem of Fatigue in Aviators.* Ross A. McFarland, Ph.D., Boston (by invitation)

INTERMISSION

3:30 *Treatment of Gunshot Wounds of the Brain.* Dr. Gilbert Horrax, Boston.

3:50 *A Report of Newer Work on the Shock Problem.* Dr. Walter B. Cannon, Boston.

4:10 *War Neuroses.* Dr. Douglas A. Thom, Boston.

4:30 *Blood and Blood Substitutes in the Treatment of Hemorrhage, Secondary Shock and Burns.* Dr. Stuart Mudd, Philadelphia.

LADIES' PROGRAM

For the ladies in the families of the members of the Massachusetts Medical Society, a most interesting program has been arranged by the Ladies' Committee, consisting of Mrs. Walter G. Phippen, Mrs. William T. O'Halloran, Mrs. Bennett F. Avery, Mrs. Theodore L. Badger, Mrs. Edmund J. Butler, Mrs. William Dameshek, Mrs. David C. Ditmore, Mrs. John G. Downing, Miss Mary L. Field, Mrs. Reginald Fitz, Mrs. John A. Foley, Mrs. Arthur J. Gorman, Mrs. Thomas H. Lanman, Mrs. Roger I. Lee, Mrs. Frederick J. Lynch, Mrs. Wilfrid C. Macdonald, Mrs. Frank W. Marlow, Jr., Mrs. Donald Munro, Mrs. Robert N. Nye, Mrs. Frank R. Ober, Mrs. Eugene E. O'Neil, Mrs. John W. Spellman, Mrs. Martin H. Spellman, Mrs. A. Warren Stearns, Mrs. Augustus Thorndike, Jr., and Mrs. Charles F. Wilinsky.

WEDNESDAY, MAY 21

All ladies should register at the desk in the main lobby of The Copley-Plaza. In the afternoon there will be a visit to the Isabella Stewart Gardner Museum, Fenway Court, including a tour of the museum, music, a reception and tea; admission to the museum is \$0.75. Busses will leave The Copley-Plaza at 2:15 p.m., and there will be no charge for transportation. Those wishing to play golf on Wednesday should make arrangements at the registration desk.

Dinner will be held at the Ritz Roof, Hotel Ritz Carlton, at 7:30 p.m. Mrs. Phippen, Mrs. Lee and the wives of the district presidents will meet the guests. During and after dinner there will be a floor show. The cost of the dinner tickets is \$2.50.

THURSDAY, MAY 22

The registration desk will be open from 9:00 a.m. to 12:00 m. At 10:00 a.m. busses will leave The Copley-Plaza on a most interesting trip to the South Shore. Stops will be made at the Dorothy Quincy House and the Adams Mansion, which was the home of two United States presidents, in Quincy. At Hingham, the Cushing Homestead, which was built in 1636, will be visited by invitation, and a stop will be made at the historic Old Ship Church. Luncheon will be served at Hugo's in Scituate at 1:30 p.m., for which a charge of \$1.00 will be made. The return trip will be made by way of Jerusalem Road, Cohasset. There will be no charge for transportation on this trip.

ANNUAL GOLF TOURNAMENT

The annual golf tournament of the Massachusetts Medical Society will be held at the Commonwealth Country Club on the afternoon of Wednesday, May 21.

The Burrage Bowl, emblematic of the Society championship, will again be in competition. Numerous other prizes will be offered for both net and gross scores.

Play will commence at 1:00 p.m., and the greens fee for eighteen holes will be \$2.00. If two or more rounds are played during the afternoon the fee will be \$2.50. State handicaps will be used.

Luncheon may be had at the club, and all the privileges of the club will be open to the members of the Society who enter the tournament. For additional information, telephone KENmore 2094 or a member of the Committee of Arrangements.

COMMITTEE ON POSTGRADUATE INSTRUCTION

There will be a luncheon and meeting of the district chairmen of the Committee on Postgraduate Instruction at The Copley-Plaza on Thursday, May 22, at 12:30.

MASSACHUSETTS MEDICO-LEGAL SOCIETY

There will be a meeting of the Massachusetts Medico-Legal Society in the State Salon at The Copley-Plaza on Wednesday afternoon, May 21, at 3:00.

TOXEMIA OF PREGNANCY, ASSOCIATED WITH
ECLAMPSIA AND RESULTING IN DEATH

A twenty-year-old primipara had been hospitalized in a state institution during the last four months of her pregnancy. Because of toxemia, labor was induced.

The family history and past history were not available. The patient was given adequate pre-

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

natal care after the fifth month, the urine and blood pressure being checked twice a week. Albumin did not appear until the thirty-second week, and edema appeared at the thirty-fourth week. At the twenty-second week, a blood pressure of 130 systolic, 75 diastolic, was recorded. The last week or so before induction of labor, the blood pressure was said to have gone up from 130 to 180 systolic.

Because the patient's condition was not improving, induction of labor was attempted. A catheter was inserted in the uterus and left in place for ten hours. Then, because labor had not begun, the membranes were ruptured and the cervix was packed. Six hours later, labor began. Thirty-six hours after the catheter was inserted, the patient had a severe convulsion and became unconscious. At that time the cervix was dilated to admit three fingers, and delivery was accomplished by manually dilating the cervix and applying high forceps. The fetus was dead. Ten minutes after the birth of the placenta, which was said to have been normal, the patient had a circulatory collapse and died an hour and a half later.

Comment. It is a general concept that a toxemia culminating in eclampsia and developing in a patient under constant observation during the last five months of pregnancy means only that the condition was not intelligently or adequately treated. There is no evidence in this case that there was any pelvic disproportion. Had there been any, cesarean section would have been the operation of choice. It is also possible that if there had been an appreciable rise in blood pressure occurring within twelve to twenty-four hours and a diminution of the urinary output, cesarean section again would have been indicated. Had one decided that induction was the best method of treatment, rupturing the membranes, treating the patient conservatively by the use of magnesium sulfate or veratrum viride to control the blood pressure and leaving the case absolutely alone after the membranes had been ruptured might well have resulted in a successful outcome. *Accouchement forcé* and high forceps are procedures that the unconscious eclamptic patient stands very poorly. Extreme vaginal conservatism should always be the rule.

Just what caused the circulatory collapse is hard to determine. It may well have been that the heart collapsed, either from shock or from the toxemia of the eclampsia; it is barely possible that the patient had a cerebral hemorrhage. These, however, are not very common. Unfortunately no autopsy was performed.

DEATHS

DEWEY—CHARLES G. DEWEY, M.D., of Dorchester, died April 18. He was in his eighty-second year.

Born in Hanover, New Hampshire, he attended Dartmouth College and received his degree from the Dartmouth Medical School in 1886. For four years he was assistant superintendent at the Boston City Hospital. From 1901 to 1934 he was examining physician of the mentally ill for the Institutions Department of the City of Boston, and he was associate commissioner of the Massachusetts Department of Mental Diseases from 1916 to 1934.

He was a member of the Massachusetts Medical Society, the American Medical Association and the American Psychiatric Association.

His widow, a son and two daughters survive him.

MELLEN—ELEANOR W. MELLEN, M.D., of Newton Highlands, died April 19. She was in her seventy-third year.

Dr. Mellen received her degree from the Woman's Medical College of Pennsylvania in 1903, and was a member of the Massachusetts Medical Society and the American Medical Association.

MURRAY—MICHAEL E. MURRAY, Jr., M.D., of Cambridge, died April 21. He was in his thirty-seventh year.

Born in Menominee, Michigan, he attended Notre Dame and received his degree from the Harvard Medical School in 1932. He was on the staff of the Massachusetts General Hospital, and was an assistant in the Hygiene Department of Harvard University.

Dr. Murray was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and two small daughters survive him.

MISCELLANY

CITY HEALTH CONTEST AWARDS

Ten cities were named as 1940 winners of the Inter-Chamber City Health Conservation Contest conducted annually by the United States Chamber of Commerce in co-operation with the American Public Health Association; these include Newton, Massachusetts, and Hartford and Greenwich, Connecticut. Awards were also given in 1940 for the most effective programs for the control of tuberculosis and syphilis, the contest being sponsored by the Metropolitan Life Insurance Company; the two winners in the first group were Newton, Massachusetts, and Hartford, Connecticut.

AMERICAN MEDICAL GOLFING ASSOCIATION

The American Medical Golfing Association will hold its twenty-seventh annual tournament at the Cleveland Country Club and Pepper Pike Club in Cleveland, Ohio, on Monday, June 2. The two clubs have courses of championship caliber, and the clubhouse of the Cleveland Country Club is one of the most beautiful and spacious in the country.

More than 250 members of the association are expected to take part in the thirty-six-hole competition. The hours for teeing off are from 7:30 a.m. to 2:00 p.m. The fifty prizes in the eight events will be distributed after the banquet, which will be held at the clubhouse of the Cleveland Country Club at 7:00 p.m.

All male members of the American Medical Association

are eligible and cordially invited to become members of the association; applications may be obtained from the executive secretary, Bill Burns, 2020 Olds Tower, Lansing, Michigan. Each participant in the tournament is required to present a card with his home-club handicap, signed by the club secretary, at the first tee on the day of play. No handicap over 30 is allowed. Only active members of the association may compete for prizes. No trophy is awarded to a member who is absent from the annual dinner, which is always worth waiting for.

WOMAN'S AUXILIARY, AMERICAN MEDICAL ASSOCIATION

On June 2 to 6 the Woman's Auxiliary to the American Medical Association will hold its nineteenth annual convention at Cleveland. Hotel Carter will be the headquarters. The wives of all physicians who are members of the American Medical Association and their friends are invited to attend the meetings. Requests for reservations should be sent to Dr. Edward F. Kieger, Committee on Hotels and Housing, 1604 Terminal Tower Building, Cleveland.

VINCENT MEMORIAL HOSPITAL

Plans have recently been announced for the affiliation of the Vincent Memorial Hospital and the Massachusetts General Hospital. The present building of the Vincent Memorial Hospital on South Huntington Avenue, Boston, will be sold, and a new building, still called the Vincent Memorial Hospital, will be built on the grounds of the Massachusetts General Hospital. Dr. Joe V. Meigs, chief-of-staff at the Vincent Memorial Hospital, and the other physicians on the staff will continue to serve, and Dr. Meigs will be made head of a newly established gynecological unit at the Massachusetts General Hospital. At the meeting of the Vincent Club—an effective supporter of the Vincent Memorial Hospital—at which this announcement was made, Mr. Charles Francis Adams said that the affiliation was "a step forward in efficiency, a step forward in good management and a step forward in service to the community."

NOTES

Dr. Henry K. Beecher, associate in anesthesia, Harvard Medical School, has been appointed to a professorship at the Medical School to fill the Dr. Henry Isaiah Dorr Chair of Research and Teaching in Anaesthetics and Anaesthesia.

Dr. Israel Kapnick, '38, of Providence, Rhode Island, has been awarded the Louis E. Kirstein Fellowship at the Harvard Medical School for the summer of 1941. The fellowship, to promote "scientific medical education," was established through a gift of \$28,550 made to Harvard University by eighty-nine friends of Mr. Kirstein.

CORRESPONDENCE

TUBERCULOSIS AND GENIUS

To the Editor: In the March 6 issue of the *Journal* there appeared a review of the book, *Tuberculosis and Genius*, by Dr. Lewis J. Moorman. That review, in my opinion, not only was unkind and unfair, but also did grave injustice to Dr. Moorman and his work.

About half the space given to the book review was occupied by a harangue about the various abuses of present-day management of tuberculosis sanatoriums.

which was not only unwarranted in the light of facts, but was entirely missing the mark so far as Dr Moorman's book is concerned, since none of the characters considered in the biographical sketches came under strictly modern management. I shall not say anything here about such unfortunate expressions used by the reviewer, such as 'victims of tuberculosis' herded together, forced to submit to the tyrannical rules of community life and abnormal conditions imposed upon them. Who has ever relegated tuberculous patients among the morons or exalted them to the rank of geniuses? Who has branded them as dissolute erotics or beatified them as angels of chastity? It is true that a London physician, Dr Gwilym, once proposed castration as a method of treatment for pulmonary tuberculosis. But that was in 1857. Strong objections being raised, he desisted. As to clinicians who feel 'the urge to become amateur psychiatrists,' I think that chest specialists are perfectly justified in studying their patients as best they can in that respect and in noting carefully their emotions, reactions and adjustments during the course of their disease. All that, however, has nothing to do with Dr Moorman's book.

Are the diagnoses made by Dr Moorman correct? Is there a relation between tuberculosis and genius? And, if there is, what is the nature of that relation? Those are the questions raised by Dr Moorman's essays.

To make a retrospective diagnosis on a person dead long ago is not any different than to study any other point of history, and the two should be governed by the same rules. All the records extant should be carefully and critically examined before conclusions are drawn. Now, everyone familiar with the study of history knows that, even when all the evidence has been gathered, it is very often impossible to arrive at deductions that are certain, positive and final. One must often content oneself with conclusions that are *most probable*, or only *probable*, or simply *possible*. The same holds true of a diagnosis. If I must show that a man has had a positive sputum before I can call him tuberculous, then none of Dr Moorman's characters had tuberculosis. Nobody had tuberculosis before Koch discovered the bacillus. Did Stevenson have it? I must doubt it even if all the rest of the evidence points toward it, because, if I am not mistaken, Trudeau failed to examine Stevenson's sputum when he took the latter to his laboratory.

The fact that all the diagnoses made by Dr Moorman can be questioned is not Dr Moorman's fault. It is the fault of history. History is not an exact science, like mathematics, and never will be. It deals with human beings, and its conclusions are never definitive and can always be questioned. For example, historians all over the world have not arrived yet at a positive and certain conclusion about the true cause of World War I. Likewise the man interested in medicohistorical studies has to be satisfied with diagnoses that are sometimes only probable, sometimes only possible.

The reviewer contends that Dr Moorman's excursions into history and his diagnoses are based on assumptions. Not at all. They are based on the available records. Has Dr Moorman examined *all* the available records? That is what should have been discussed. The book should have been studied like a book of history, with the methods of the historian. The reviewer has failed to do that. More than that after claiming that Dr Moorman walks on very thin ice he himself goes out on thinner ice, and proposes, for Voltaire, a diagnosis of bronchiectasis. There are at least thirty different medicohistorical studies about Voltaire's health, his diseases and his last illness. If

there is a diagnosis that is *most improbable*, it is that of bronchiectasis.

What is the relation between tuberculosis and genius? That question calls for another and more inclusive one. What are the relations between the body and the mind? Genius is only the mind working in a superlative way. It is a truism to say that the body and the mind are closely interrelated and that states of mind are often dependent on states of body and, conversely, that bodily changes often follow mental changes. It is not the place here to inquire into the modifications wrought on the mind and the personality by changes in the secretions of the endocrine glands, by chronic infections, by intoxications of long duration and by other factors. But let us take one example: the thyroid gland. We all know the mental changes that take place when the secretions of this gland begin to decrease: slowness, dullness, apathy. If the function of the gland continues to slow up, we may have actual cretinism. The reviewer says that genius transcends contingencies. If suffering from the most disabling form of tuberculosis for years is a contingency, then having a thyroid gland that does not secrete is also a contingency. I should like to see a genius transcend that one!

Let us take another example. A composer of talent, or of genius, is occupied in writing a symphony. In the course of the creation of that symphony, a virulent, destructive tuberculous process invades one of his lungs and destroys it. Who will say that the style of his music will not be affected by what is going on in his chest?

Dr Moorman never claimed that tuberculosis is the cause of genius, or gives genius to a man, or adds to the genius of a man. Is there anything more evident and obvious than the fact that having tuberculosis does not presuppose having genius? I feel a little sympathy for Dr Moorman. I myself, some time ago, in an article about a man who had had tuberculosis, asked, merely asked, if there was not some relation between tuberculosis and the creative mind. Another book reviewer and his prompter tried to have me say that tuberculosis was a causative factor in the production of genius.

The reviewer denies that there is any relation between tuberculosis and genius, but he is willing to admit that the 'artistic temperament' can be influenced by syphilis. He does not demonstrate it, however. When he has succeeded in demonstrating that syphilis can influence an artist, he will have demonstrated that tuberculosis can also influence an artist. The reviewer shows confusion on another point. I put side by side two sentences from his review: 'Knowing the artistic temperament, one may be permitted to suggest the existence of a sprinkling of spirochetes. And, 'To tell them that the creative power of genius is enhanced by the toxins of such or such a germ would seem to be unjustifiable.' Isn't there contradiction here?

As to Balzac, DeQuincey and Poe having written beautifully without coffee, opium and alcohol, that is not the question. The question is, Would they have written what they wrote as they wrote it, without coffee, opium and alcohol? A man of genius is born with his genius. The manifestation of his genius is conditioned and determined by several external factors, among which are the development of his body, his health, his diseases and so forth.

To conclude I think that Dr Moorman should be congratulated. A man who has had long experience in tuberculosis work, he has written a most interesting book about a certain aspect of tuberculosis. It is not a work of eru-

dition or research. It was not intended to be one. It is a captivating study of the lives of ten men and women handicapped by a long debilitating illness. In the words of Dr. Max Pinner, who has written, in my opinion, the best and most sympathetic review of Dr. Moorman's book, it should "reach many patients and many physicians . . . it will teach physicians a deeper sympathy and understanding for their charges . . . it belongs in the patients' library of every tuberculosis ward." The National Tuberculosis Association has recognized the value of the book and has selected it for distribution among its members.

GABRIEL NADEAU, M.D.

Rutland State Sanatorium,
Rutland, Massachusetts.

PHARMACEUTICAL ADVERTISING

To the Editor: The editorial in the March 13 issue of the *Journal* that deals with vitamins is very interesting, since it tells the medical practitioner that he has given over, perhaps by force, his therapy to the purveyors of proprietary preparations—in this case, vitamins.

Every line in the editorial is full of truth, and if the average physician is anxious to keep away from the poor-house where he is gradually being forced by many unethical so-called "ethical" houses, he should do what I have been doing in the last seven years.

I do not prescribe anything manufactured or distributed by a concern that advertises its products in a publication that is read by the general public, since it is my belief that such an act on the part of the manufacturer or distributor constitutes the illegal practice of medicine and is thus an interference with the livelihood of the legitimate practitioner. There are a few manufacturers who do not advertise to the general public, nor do they furnish display signs for the use of counter-prescribing druggists. It is therefore the duty of the average physician to confine his prescribing to articles of these manufacturers. By doing this the physician will be able to preserve his own practice and will at the same time aid those who are helping him.

A. PRAGLIN, M.D.

26 Davis Street,
Boston.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on January 14, 1941, with Dr. Joseph C. Aub presiding.

The first case was that of a forty-one-year-old man who had entered the hospital three months previously because of epigastric and left-upper-quadrant distress. A gastrointestinal series revealed a carcinoma of the upper end of the stomach, and total resection was subsequently carried out, with smooth convalescence. Roentgenographic studies eleven days postoperatively revealed a well-functioning stoma; when the patient was discharged he was asymptomatic. A month later the patient was bothered by heartburn, for which dilute hydrochloric acid and antacid powders were administered, with relief in a week. A recurrence of these symptoms in another ten days was not amenable to this therapy, and the patient also began to be bothered by regurgitation, particularly of saliva. He voluntarily started on a soft-solid diet without relief but with the loss of 15 pounds in weight until the present admission. Physical examination, the blood chemical

findings and a gastrointestinal series were negative except for some abnormality of swallowing during the last test. This was not true regurgitation but largely difficulty in swallowing saliva. Atropine in doses of 0.6 mg. daily caused a decrease in the amount of saliva, and 10 units of insulin three times daily improved his failing appetite. No sympathetic symptoms were present, nor was the salivation associated with nausea.

Dr. E. S. Emery suggested that radical gastric surgery may often be associated with autonomic symptoms resulting from an accentuation in a susceptible person of an underlying autonomic imbalance. These manifestations may take the form of sweating, dizziness or an elevation of blood pressure after meals. Dr. Robert Zollinger stated that the much-discussed problem of anemia seldom develops, whereas diarrhea or obstruction due to a poorly functioning stoma is quite frequent. This was the first case of salivation, and one other patient experienced postprandial rhinitis. Dr. Arturo Rosenbluth expressed surprise that atropine did not have a better effect. He stated that abnormal afferent impulses might explain the phenomena. The rate or even presence of regrowth of afferent fibers following gastric resection is an unknown quantity.

The medical case was that of a fifty-nine-year-old man who entered the hospital because of weakness and unsteadiness of his legs for several weeks. Several years previously he had had gonococcal urethritis, which had been "cured" by local treatment. One year before entry weakness and lameness of the lower extremities were first noted. Five weeks before entry he realized that the heat of a stove was not felt with his left hand, and he began to have poor control of finer movements and speech. Blood and cerebrospinal-fluid Wassermann tests were positive at an outlying hospital. Neurologic examination on entry revealed hyperactive tendon reflexes, a positive Hoffmann sign bilaterally, and poor position sense and heel-to-shin test. There was an elevated sedimentation rate. The cerebrospinal fluid revealed a positive Wassermann reaction and a first-zone gold-sol curve. The blood Wassermann reaction was negative three times and positive twice. Bismuth and neoarsphenamine therapy was instituted. Dr. John Romano suggested that the unusual combination of signs was due to a lateral medullary thrombosis superimposed on a diffuse syphilitic meningoencephalitis.

The speaker of the evening was Dr. Rosenbluth, his subject being "A Physiologic Analysis of Abnormal Neuromuscular Function." Dr. Rosenbluth defined neuromuscular disorders as a "deficiency in the performance of motor function due to a lesion below the motor neurone." He stated that the purpose of his address was an attempt to classify such disorders on a physiologic rather than the usual morphologic basis, and to propose some tests for the approval of the clinician.

As an introduction, the speaker showed a schematic plan of the neuromuscular response in which a nerve impulse sets free a quantum of acetylcholine, which causes a muscle impulse (similar in nature to a nerve impulse); this, in turn, results in a contractile response, which is the clinical but not the physiologic end point. The latter involves the inactivation of acetylcholine by cholinesterase, which is found at the site of release and causes a breakdown into acetic acid, inactive choline and a recovery process. It was pointed out that an identical response can be brought about in what is termed a "contracture" when acetylcholine exerts its effect directly without a muscle impulse.

The mechanism whereby acetylcholine causes a muscle

impulse was then discussed. In any nerve-muscle preparation, there is a threshold below which acetylcholine produces no response, but there is also an upper limit to the effective range above which this substance becomes paralytic. Usually there is only a single response to a given amount of acetylcholine because cholinesterase causes so rapid a breakdown that the level of mediator is subthreshold by the time the muscle ceases to become refractory. The failure of a muscle to respond in any case may be due to an elevated threshold in the presence of a normal amount of acetylcholine (curare), or to a diminished amount of acetylcholine in cases in which the threshold remains essentially normal (certain types of fatigue). In Wallerian degeneration the transmission of nerve impulses proceeds for some time before suddenly ceasing. Here the nerve impulses remain normal, but the acetylcholine output eventually falls below the threshold value and responses cease.

The paralytic range of acetylcholine can be demonstrated experimentally by neutralizing cholinesterase with eserine. In this case there is no breakdown of acetylcholine, and a summation of the substance results from repeated stimulations. Therefore, a curare and eserine may achieve the same result by entirely different mechanisms and it becomes clinically important in a given case of neuromuscular dysfunction to know which type of paralysis is present, for adding acetylcholine aids the first condition but merely aggravates the second.

Dr Rosenbluth then discussed so-called 'fatigue'—a poorly defined physiologic as well as clinical term. High rate stimulation (60 per second) of a nerve-muscle preparation results in fatigue of transmission because of too little acetylcholine. Stimulation at a slow rate (2 to 4 per second), on the other hand, causes contractile fatigue. Here the response, no matter how far diminished, never entirely disappears, in contrast to the previous type of fatigue. Transmission is intact, but there is a depression of the contractile system.

A classification of clinical neuromuscular disorders is suggested on this physiologic basis. Under 'hypodynamic' effects would be classified atonia, ataxia, fatigue and paralysis. These might be due to transmission defects in which acetylcholine is either below the threshold level or above the paralytic level, or they might result from an impairment of the motor system in the muscle itself. On the opposite side would be the 'hyperdynamic' conditions such as convulsions, spasm, myoclonia and myotonia. Such conditions might be due to nerve changes such as can be caused by veratrine¹ when the responses of nerve become repetitive, changes in transmission (possible but improbable), when the action of acetylcholine may be prolonged within the effective range, and dysfunction of the contractile mechanism whereby the response to a given stimulus is greater than normal.

Finally Dr Rosenbluth suggested certain clinical tests that he considered applicable to neuromuscular disorders to determine the site and type of pathologic physiology. To decide whether a disease is central or peripheral the carrying out of novocain block and the stimulation of the nerve at various frequencies peripherally to the block, the study of the acetylcholine thresholds of normal and neurologic patients, the administration of eserine to determine whether there is improvement or aggravation of symptoms and signs, the use of subparalytic doses of curare, biopsy and cholinesterase-content determinations of muscle and of blood—these may be difficult to interpret, owing to the heterogeneous distribution of the enzyme in muscle.

The discussion was inaugurated by Dr John Romano whose only question concerned the variable effects of

quinine obtained in myotonic conditions and the physiologic basis for these effects. Dr Rosenbluth replied that this drug is now known to be similar to curare in certain respects and to eserine in others. Therefore, complicated reactions may ensue, and the end results depend on the original balance in the neuromuscular system.

Dr Henry R. Viets, acknowledging the desirability for improved clinical tests in neuromuscular disorders, advanced certain practical objections to the speaker's suggested tests. In the first place, there are too few peripheral nerves available for stimulation. Cholinesterase is difficult to detect and quantitate in the situations in which it is desirable. It is impractical to treat with acetylcholine, owing to its ready destruction in the body. In regard to treatment of some of these disorders, Dr Viets stated that prostigmine and other anticholinergic drugs seem to be all right clinically. In Thomson's disease there appears in most cases to be improvement with quinine and aggravation of the clinical picture with prostigmine. The important relation of endocrinology to the entire group of neuromuscular disorders was emphasized, and Dr Viets reminded the audience that the first description of myasthenia gravis recommended pregnancy as a cure.

In reply, Dr Rosenbluth suggested that the easily accessible ulnar nerve be used for stimulation on the basis that there is probably generalized neuromuscular involvement, even in such seemingly localized conditions as myasthenia gravis and scapulohumeral muscular atrophy. Dr Viets agreed with the probability of generalized subclinical involvement and the feasibility of ulnar stimulation.
